

# NVIDIA CAPTURE SDK

PG-06183-001\_v07.1 | October 2018

## Programming Guide

## DOCUMENT CHANGE HISTORY

PG-06183-001\_v07.1

Version	Date	Authors	Description of Change
0.7	5/9/2011	BO	Initial draft
0.8	10/18/2011	JB	Adding information about NVFBC_TARGET_ADAPTER
0.9	1/2/2012	AC	Updated for GRID Toolkit version 1.1
0.91	7/20/2012	AC	Updated for Monterey Toolkit version 1.2
0.92	8/3/2012	JB	Removed NvEncodeAPI.dll references
1.0	5/21/2013	BO	Updated to match V2.0 of GRID SDK
2.1	7/29/2013	SD	Update to include GRID SDK V2.1 features
2.3	3/6/2014	AR	Update to include GRID SDK V2.3 features
3.0	7/8/2014	SD	Update for GRID SDK 3.0
4.0	5/12/2015	SD	Update for GRID SDK 4.0, include INVFBCHWEncoder interface, deprecated NVFBCTOH264HWEncoder interface.
4.1	7/9/2015	SD	Update to include NVFBCToDX9Vid interface, remove Tegra decode guide
4.1.1	11/17/2015	EY	Added section 2.9.1.6 with details on how to change the bitrate dynamically.
5.0	2/5/2016	SD	Update for NVIDIA Capture SDK 5.0, Added Section 2.11 to describe usage of difference maps, Added deprecation note for INVFBCHWEncoder interface
5.0	7/26/2016	SD	Update for NvFBCFrameGrabInfo::dwDriverInternalError diagnostic usage
6.0	1/20/2017	SD	Added information for the Capture SDK 6.0 release.
6.1	5/10/2017	SD	Update NVFBC DiffMap description
7.0	2/22/2018	SD	Update NVFBC Classification Map description
7.1	9/24/2018	SD	Remove references to deprecated interfaces

# Chapter 1. OVERVIEW

The NVIDIA® Capture Software Development Kit, previously called GRID™ SDK, is a comprehensive suite of tools for NVIDIA GPUs that enable high performance graphics capture and encoding. This Programming Guide describes how to use the various NVIDIA Capture SDK interfaces available on GRID, Quadro, and specific Tesla Products.

## 1.1 GPU ACCELERATED READBACK AND ENCODE

The NVIDIA Capture SDK includes two API interfaces for high performance readback of rendered content from the GPU and video encoding on the GPU:

### 1.1.1 NVFBC - NVIDIA Framebuffer Capture

The NVIDIA Framebuffer Capture (NVFBC) API captures and optionally compresses the entire Windows desktop or full-screen applications running on the supported Operating Systems (For list of Operating Systems, please refer to the SDK release notes). It essentially provides the same output as a real connected monitor to the GPU: a full desktop, with application windows, menu bar, composited overlay and hardware cursor. As such, NVFBC is ideally suited to *desktop capture and remoting*.

NVFBC has many advantages over existing methods of framebuffer capture. It is resilient to Aero DWM (enable/disable) changes and resolution changes. It operates asynchronously to graphics rendering because it is able to use the dedicated hardware compression and copy engines on the GPU. It delivers frame data to system memory faster than any other display output or other readback mechanisms all while having minimal impact on the rendering performance.

*NVFBC is described in Chapter 2.*

## 1.1.2 API Reference documents

Details of APIs, parameters, etc. are documented in the API reference documents “*NVFBBC.chm*” that are installed with the NVIDIA Capture SDK.

The term “*NVFBBC API Reference document*” used in this programming guide refers to *NVFBBC.chm*.

# Chapter 2. NVFBC - FRAMEBUFFER CAPTURE

**NVIDIA Framebuffer Capture (NVFBC)** is a high performance, low latency API for reading back display frames from one or more GPU *display heads*. NVIDIA GPUs typically support at least two display heads, and these are usually associated with a physical display output such as a DVI, DisplayPort, or HDMI connector. NVFBC provides essentially the same output one would see on a monitor connected to the GPU: a full desktop, with application windows, menu bar, composited overlay and hardware cursor. By operating asynchronously to graphics rendering and using dedicated hardware compression and copy engines in the GPU, NVFBC delivers frame data to CPU-based applications faster than any other display output or readback mechanism, with minimal impact on rendering performance.

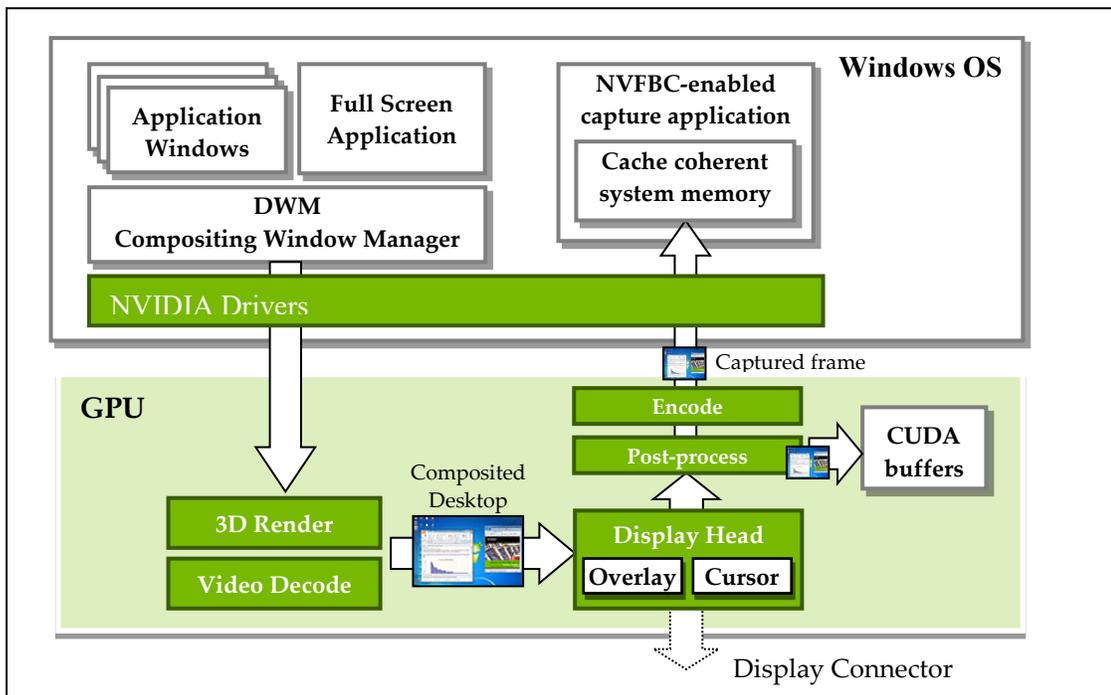

Figure 1 NVFBC framebuffer capture

NVFBC is supported on the Windows 7, Windows 8, Windows 8.1, & Windows 10 operating systems, and offers these features:

- ▶ Automatic capture of on-screen updates (graphics updates or mouse moves)
- ▶ Full operation through screen resolution changes, and Windows Aero on/off
- ▶ Compositing of hardware cursor and overlay with the base desktop image
- ▶ Color space conversion
- ▶ Cropping and scaling
- ▶ Pixel and tile-based differencing
- ▶ Stereoscopic capture
- ▶ Output of H.264 or H.265 compressed frames into cache-coherent, pinned system memory
- ▶ Output of uncompressed frames into cache-coherent, pinned system memory; this mode is ideally suited for use with CPU-based post-processing / compression implementations.
- ▶ Output of uncompressed frames into D3D9-mapped buffers in the GPU framebuffer; this mode is ideally suited for use with D3D9 post-processing / compression implementations<sup>1</sup>.
- ▶ Output of uncompressed frames into CUDA-mapped buffers in the GPU framebuffer; this mode is ideally suited for use with CUDA-based post-processing / compression implementations<sup>2</sup>

Operation of NVFBC is straightforward: after doing one-time setup of the NVFBC API on application load, an application creates an *NVFBC object* for each GPU display head it wishes to read back from, and then enters a processing loop on each NVFBC object to read back frames from each head. Figure 2 provides an overview of the processing flow, which is described in more detail in the following sections.

 **Note:**

<sup>1</sup>*This mode works with bare metal, direct attached GPUs, and all vGPU profiles. This is the recommended path when using vGPU profiles that support two or more virtual machines sharing a single GPU. For such vGPU profiles, the CUDA driver is not available. We recommend using this NVFBC path so that capture and encode can be fully accelerated.*

<sup>2</sup>*This mode is supported in bare metal, direct attached GPUs, and vGPU profiles that limit one virtual machine. The CUDA driver is available and supported in this configuration.*

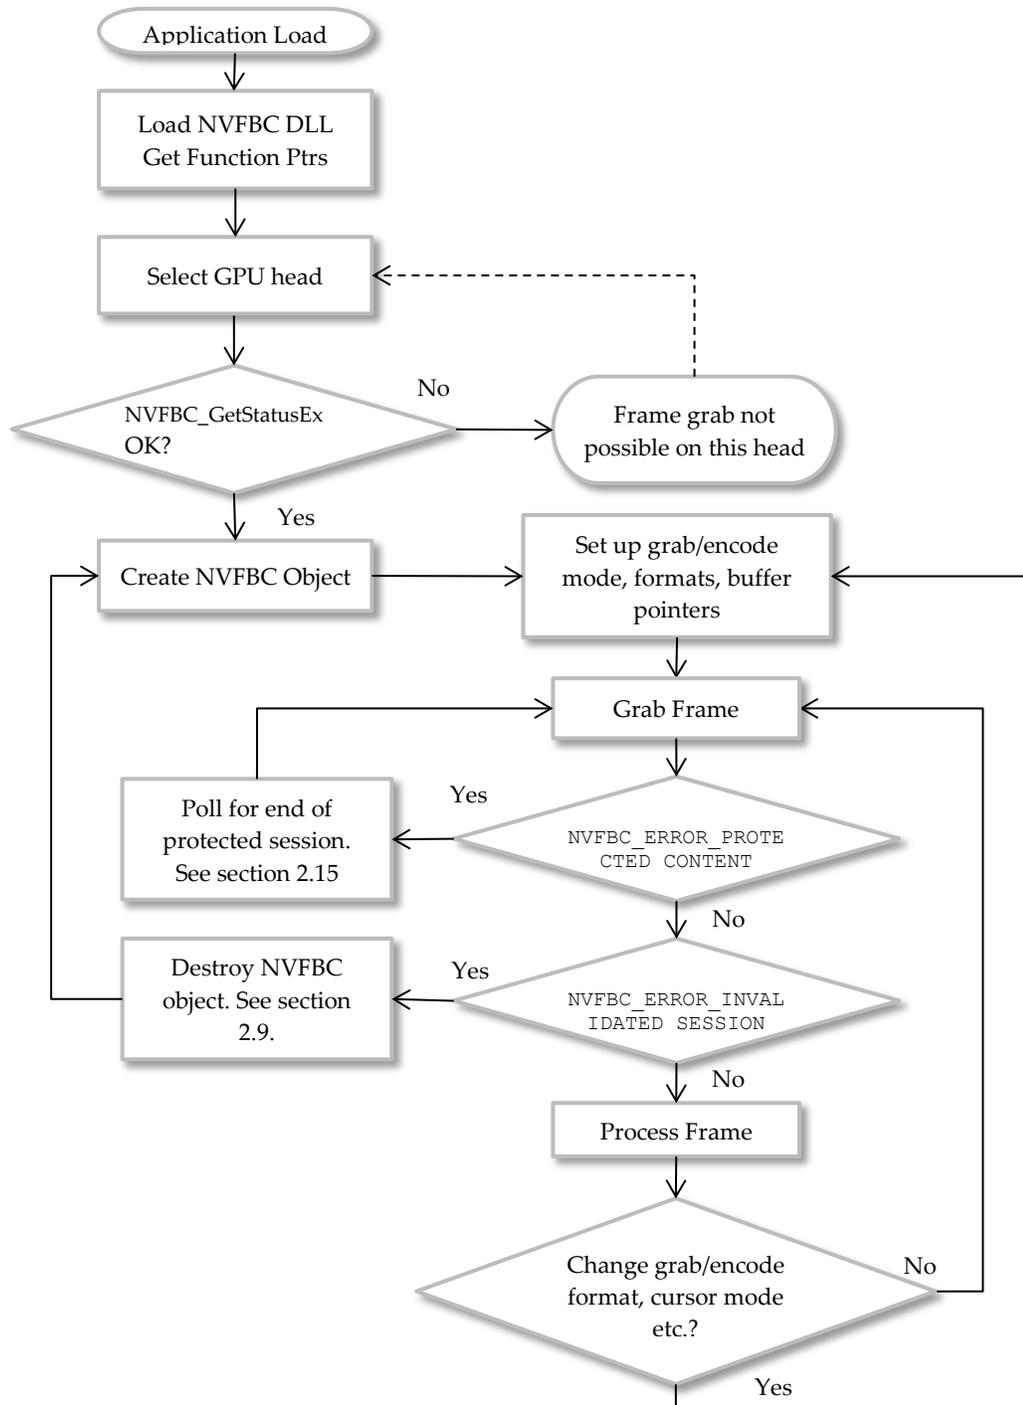

Figure 2 Overview of NVFBC application flow

## 2.1 HEADER FILES AND CODE SAMPLES

This manual provides an overview of how to use NVFBC. Further details are contained in the NVFBC header files and code samples that are included in the NVIDIA Capture SDK Toolkit:

NVFBC header files are installed in `%CAPTURESDK_PATH%\inc\NVFBC`. All NVFBC applications should include one or more of the mode-specific NVFBC header files, depending on the functionality desired:

Header file	Description
<code>NVFBC.h</code>	Top level header file included by all NVFBC applications
<code>NVFBCToSys.h</code>	Defines ToSys interface; reads back uncompressed frames to system memory.
<code>NVFBCcuda.h</code>	Defines Cuda interface; reads back uncompressed frames to CUDA-mapped buffers in the GPU's framebuffer.
<code>NVFBCtoDx9vid.h</code>	Defines the DX9Vid interface; reads back uncompressed frames to D3D9-mapped buffers in the GPU's framebuffer.

**Table 1 NVFBC header files**

The following NVFBC code samples are installed in `%CAPTURESDK_PATH%\samples\`.

Please refer to the NVIDIA Capture SDK Samples Description document for details about NVFBC samples included with the SDK.

## 2.2 PREPARING THE API FOR USE

Regardless of the mode in which an application uses the NVFBC API, the following initialization steps are required:

- ▶ Enable NVFBC Registry Settings (Every time after GRID GPU driver update)
- ▶ Load the NVFBC DLL (At application load time)
- ▶ Obtain NVFBC function pointers (At application load time)

### 2.2.1 Programmatically Enabling\Disabling NVFBC

GRID SDK 3.1 adds the ability for an NVFBC client to programmatically Enable\Disable NVFBC without needing to perform Steps mentioned in section 2.2.1 separately.

After loading the NVFBC DLL, the application should obtain a pointer to the NVFBCEnable() API. The following code snippet demonstrates how to enable NVFBC.

```
// Load NVFBC function pointer
pfnNVFBC_Enable = (NVFBC_EnableFunctionType)
    GetProcAddress(handleNVFBC, "NVFBC_Enable");
// Check NVFBC Status
NVFBCStatusEx status;
pfnNVFBC_GetStatusEx(&status);
if (!status.bCurrentlyCapturing && !status.bIsCapturePossible)
{
    // NVFBC Capture has not been enabled. Try Enabling it.
    NVFBCRESULT res = pfnNVFBC_Enable(NVFBC_STATE_ENABLE);
}
```

The following code snippet demonstrates how to disable NVFBC.

```
// Check NVFBC Status
NVFBCStatusEx status;
pfnNVFBC_GetStatusEx(&status);
if (!status.bCurrentlyCapturing && status.bIsCapturePossible)
{
    // NVFBC Capture has been enabled, no capture process is currently
    active. It is safe to disable NVFBC.
    NVFBCRESULT res = pfnNVFBC_Enable(NVFBC_STATE_DISABLE);
}
```

This API needs administrator privileges to work correctly. The API will return NVFBC\_ERROR\_INSUFFICIENT\_PRIVILEGES in case it is not called from a process that has Administrator privileges.

## 2.2.2 Enabling NVFBC using Registry Settings

The NVFBC technology requires a registry key to be set before the related functionality can be accessed by an application. NVFBC object creation will fail if the registry settings are not enabled.

- ▶ The procedure to enable these registry settings is described in section 3.1.3.
- ▶ An alternate method to enable NVFBC is described in section 2.2.1

This is required each time there is an update to the GRID GPU driver installed on the system where NVFBC API is being used.

## 2.2.3 Loading the DLL

The NVFBC API is accessed via a 32- or 64- bit dynamic link library (DLL), which must be loaded by the application before calling any NVFBC functions:

```
// 32-bit application
HINSTANCE handleNVFBC = ::LoadLibrary("NVFBC.dll");

// 64-bit application
HINSTANCE handleNVFBC = ::LoadLibrary("NVFBC64.dll");
```

**Note:** The NVFBC DLLs are in the NVIDIA driver directory. When shipping an application that uses the NVIDIA Capture SDKs, you do not need to ship these DLLs, as they are included in the driver. See Chapter 3 for further guidance on shipping GRID-enabled applications.

## 2.2.4 Accessing NVFBC Function Pointers

After loading the NVFBC DLL, the next step is to get pointers to the `NVFBC_GetStatusEx()`, `NVFBC_CreateEx()`, and `NVFBC_SetGlobalFlags()` functions in the DLL. This is accomplished with calls to `GetProcAddress()`:

```
// Load NVFBC function pointers
pfnNVFBC_GetStatus = (NVFBC_GetStatusExFunctionType)
    GetProcAddress(handleNVFBC, "NVFBC_GetStatusEx");

pfnNVFBC_Create = (NVFBC_CreateFunctionExType)
    GetProcAddress(handleNVFBC, "NVFBC_CreateEx");

pfnNVFBC_SetGlobalFlags = (NVFBC_SetGlobalFlagsType)
    GetProcAddress(handleNVFBC, "NVFBC_SetGlobalFlagsEx");

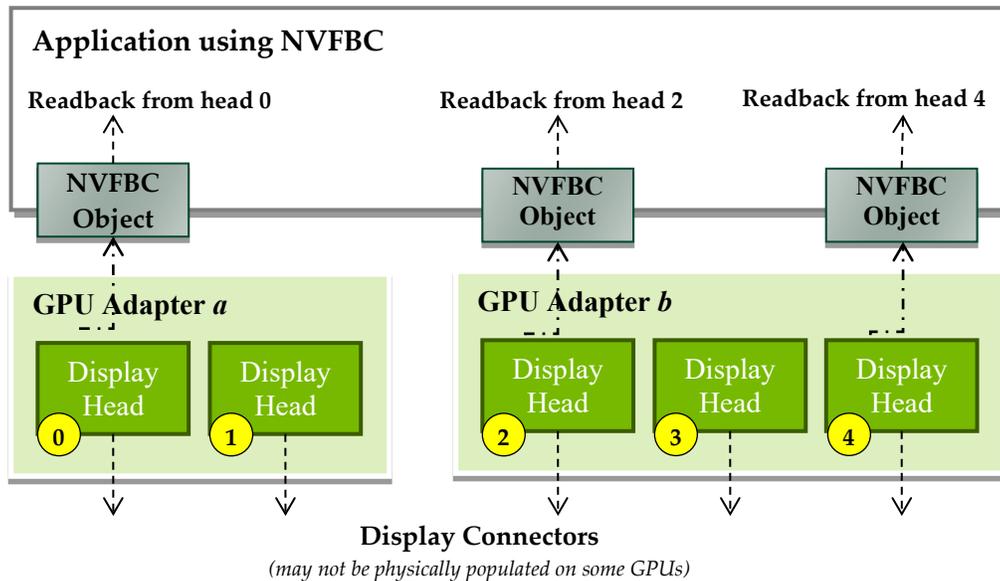

pfnNVFBC_Enable = (NVFBC_EnableFunctionType)
    GetProcAddress(handleNVFBC, "NVFBC_Enable");
```

## 2.3 SELECTING A GPU HEAD FOR READBACK

The NVFBC API reads back frames from one or more GPU *display heads*. Exactly one display head can be associated with an NVFBC session object. This association needs to be established while creating the NVFBC object, and it stays bound throughout the session lifetime. Note that exactly one NVFBC session can be associated with a display at any given time, making this a 1:1 association.

NVIDIA GPUs typically support at least two display heads, and there may be multiple NVIDIA GPUs present in the system.

Figure 3 shows an example system with two NVIDIA GPUs, each with multiple display heads. An application is reading back frames from one display head on the first GPU, and two display heads on the second GPU, and has created three NVFBC objects for this purpose.

**n** Direct3D9 ordinal adapter ID: set NVFBC\_TARGET\_ADAPTER to this value at NVFBC object creation time, to select the head to be associated with the object.

**Figure 3 NVFBC objects association with GPU display heads**

Display heads are numbered using the ordinal adapter identifier value assigned by Direct3D9. The number of attached D3D9 adapters can be acquired by calling `IDirect3D9::GetAdapterCount()`. To get information about specific adapters `IDirect3D9::GetAdapterMonitor()` or `IDirect3D9::GetDeviceCaps()` should be called.

**Note:** For detailed code samples showing how to enumerate adapters using Direct3D9 and cross-reference with those returned by GDI, and how to enable display heads that do not have monitors attached to them, see the white paper *Displayless Multi-GPU on Windows 7*, which is included with the GRID Toolkit.

The client can select a GPU head for readback by setting up NVFBC using either of the following methods:

- ▶ Initialize a D3D9 device using Direct3D9 ordinal adapter identifier of the display head to be read back and pass the `IDirect3DDevice9` object to `NVFBCreateEx` as `NVFBCreateParams::pDevice`
- ▶ If the client does not want to manage a D3D9 device, the client should set `NVFBCreateParams::pDevice` to `NULL` and Direct3D9 ordinal adapter identifier of the display head to be read back should be passed to `NVFBCreateEx` as `NVFBCreateParams::dwAdapterIdx`

## 2.4 VERIFYING NVFBC STATUS

Once a display head has been selected, verify the status of the NVFBC interface for that head by calling `NVFBC_GetStatusEx()`, with the parameter `NVFBCStatusEx::dwAdapterIdx` set to the selected adapter ordinal:

```
NVFBCStatusEx status;
...
// Get NVFBC status

pfnNVFBC_GetStatusEx(&status);
```

Please refer to the API reference document for details regarding the `NVFBC_GetStatusEx()` API.

It is safe to call `NVFBC_GetStatusEx()` multiple times to poll for detecting completion of NVFBC enable\disable operation.

## 2.5 CREATING NVFBC OBJECTS

All NVFBC readback operations are exposed as methods in NVFBC classes. Distinct classes are used to support the different readback modes supported by NVFBC (to system memory, to CUDA buffers, and H.264 encode). After using `NVFBC_GetStatusEx()` to verify that readback is possible on a GPU head; the next step is to create an NVFBC class object associated with the GPU head.

An NVFBC object is associated with exactly one GPU display head. Selecting a head for readback is described in section 2.3.

**Note:** At most one NVFBC object can be active on a display head at any given time.

NVFBC objects cannot be created while any application is currently running in fullscreen mode on any head. NVFBC-enabled applications should typically create NVFBC objects for available display heads at system initialization time, before any applications run in full screen mode.

To create an NVFBC object, allocate variables to store the maximum display width and height, then call `NVFBC_CreateEx()` to create the object. The example below creates an `NVFBC_TO_SYS` object, to read back data directly to system memory, but the create call is similar for all classes of NVFBC object:

```

NVFBCRESULT (NVFBCAPI * NVFBC_CreateFunctionExType)
(void * pCreateParams);

// Example of usage:

// NVFBC_TARGET_ADAPTER env variable previously set...
NVFBCCreatParams createParams = {0};
createParams.dwVersion = NVFBC_CREATE_PARAMS_VER.
createParams.dwInterfaceType = NVFBC_TO_SYS;
createParams.dwMaxDisplayWidth = -1;
createParams.dwMaxDisplayHeight = -1;
createParams.pDevice = pD3DDevice; //Pointer to app's
D3DDevice
createParams.pPrivateData = NULL;
createParams.dwPrivateDataSize = 0;
createParams.dwInterfaceVersion = NVFBC_DLL_VERSION;

createParams.pNVFBC = NULL; //OUT, pointer to requested NVFBC object

NVFBCRESULT result;
result = pfnNVFBC_CreateEx(&createParams);

```

The `createParams.dwInterfaceType` parameter specifies the type of NVFBC object to be created;

dwCaptureType value	Notes
NVFBC_TO_SYS	Reads back frames to locked, cache-coherent buffers in system memory. See section 2.5.2.
NVFBC_SHARED_CUDA	Reads back frames in ARGB format to CUDA-mapped buffers resident in the GPU's framebuffer. See section 0.
NVFBC_SHARED_CUDA_YUV420P	Reads back frames in YUV420p format to CUDA-mapped buffers resident in the GPU's framebuffer. See section 0.
NVFBC_TO_HW_ENCODER	Reads back compressed video frames to locked, cache-coherent buffers in system memory. See section <b>Error! Reference source not found..</b>

**Table 2 NVFBC capture types**

The `createParams.dwMaxDisplayWidth` and `createParams.dwMaxDisplayHeight` parameters are used to return a maximum supported resolution supported by the NVFBC interface.

The `createParams.pPrivateData` argument is reserved for future use, and should be passed as `NULL`.

If successful, the `NVFBCCreateEx()` call returns `NVFBC_SUCCESS`, with a pointer to a newly-created NVFBC object in `CreateParams.pDevice`. Otherwise the call returns an error code, as enumerated in `NVFBC.h` as `NVFBCRESULT`. An error can be caused by:

- ▶ An NVFBC object already active for the head indicated by `NVFBC_TARGET_ADAPTER`.
- ▶ An application running in full screen mode on any display head.

## 2.5.1 Maximum supported resolution

The maximum supported display resolution returned from the `NVFBC_CreateEx()` call is a static property of the NVFBC interface, and is deliberately larger than the typical maximum resolution supported on a single GPU display head. This allows NVFBC to internally pre-allocate readback buffers, and handle dynamic resolution changes during capture/readback without needing to reallocate buffers.

Similarly, applications using NVFBC may wish to use the reported maximum resolution to size and pre-allocate any data buffers they use for handling readback data.

## 2.5.2 Frame grab info structure

Information about the grabbed frame is returned in the `NVFBCFrameGrabInfo` structure passed to the call. Please refer to the API reference for details regarding `NVFBCFrameGrabInfo` members.

## 2.6 CAPTURING TO SYSTEM MEMORY

To capture uncompressed frames to system memory, create an NVFBC object from the NVFBCToSys class by specifying:

```
CreateParams.dwInterfaceType = NVFBC_TO_SYS;
```

Please refer to NVFBCToSys Object definition in the NVFBC API Reference document.

### 2.6.1 Setting up the NVFBCToSys object

Before frames can be grabbed, the NVFBCToSys object requires a setup call, NVFBCToSysSetup(), to specify the target capture mode and the required grab format. The NVFBCToSysSetup() method returns pointers to buffers that will contain readback data and difference maps. NVFBCToSysSetup() may subsequently be called again for an NVFBCToSys object, any time the application wishes to change the capture mode or grab format.

Please refer to NVFBC API reference document for details regarding NVFBC\_TOSYS\_SETUP\_PARAMS struct.

```
NVFBCRESULT NVFBCToSysSetUp(NVFBC_TOSYS_SETUP_PARAMS *pParam)

//! Example of usage:

unsigned char *pBuffer = NULL;
unsigned char *pDiffMap = NULL;

NVFBC_TOSYS_SETUP_PARAMS setupParams = {0};
setupParams.dwVersion = NVFBC_TOSYS_SETUP_PARAMS_VER;
setupParams.bWithHWCursor = FALSE;
setupParams.bDiffMap = TRUE;
setupParams.eDiffMapBlockSize = (NvU32) NVFBC_TOSYS_DIFFMAP_BLOCKSIZE_128X128;
setupParams.eMode = NVFBC_TOSYS_ARGB;
setupParams.ppBuffer = &pBuffer;
setupParams.ppDiffMap = &pDiffMap;

NVFBCRESULT result;
result = NVFBCToSys->NVFBCToSysSetUp(&setupParams);
```

If successful, NVFBCToSysSetup() returns NVFBC\_SUCCESS, and the object is now ready for frame grabbing. Otherwise it returns one of the errors enumerated in NVFBCRESULT.

### 2.6.1.1 Capture mode

The `NVFBC_TOSYS_SETUP_PARAMS::eMode` parameter is a capture mode that specifies the pixel format in which frame captures will be returned. Please refer the NVFBC API reference for details regarding `NVFBCToSysBufferFormat` enum.

### 2.6.1.2 Hardware cursor handling

The `NVFBC_TOSYS_SETUP_PARAMS::bWithHWCursor` parameter controls hardware cursor compositing: if specified as `TRUE`, any active hardware cursor is composited into read back frames, otherwise it is not. If a software cursor is active, this will be composited into the frame regardless of this parameter setting.

### 2.6.1.3 Readback buffer

The `NVFBC_TOSYS_SETUP_PARAMS::ppBuffer` parameter is a pointer to pointer to a buffer that will contain the read back frame data, in the format specified by the capture mode in `setupParams.eMode`. Note that NVFBC allocates the buffer for the frame data, the application simply passes a `void **` argument to receive a pointer to the NVFBC-allocated buffer.

### 2.6.1.4 Difference maps

The `NVFBC_TOSYS_SETUP_PARAMS::ppDiffMap` parameter is a pointer to a pointer to a buffer (allocated by NVFBC) that will contain a frame-to-frame difference map whenever a frame is read back. If your application will not make use of difference maps, this argument may be passed as `NULL`.

Please refer to section 2.6.2.3 for more information.

## 2.6.2 Grabbing frames with NVFBCToSys

To grab a frame with NVFBCToSys, call `NVFBCToSysGrabFrame()`:

```
NVFBRESULT NVFBCToSysGrabFrame(NVFBCTO_SYS_GRAB_FRAME_PARAMS *pParam);

// Example of usage:

NVFBFrameGrabInfo frameGrabInfo;

NVFBCTO_SYS_GRAB_FRAME_PARAMS grabFrameParams = {0};
grabFrameParams.dwVersion = NVFBCTO_SYS_GRAB_FRAME_PARAMS_VER;
grabFrameParams.dwFlags = NVFBCTO_SYS_NOFLAGS;
grabFrameParams.dwTargetWidth = -1;
grabFrameParams.dwTargetHeight = -1;
grabFrameParams.dwStartX = 0;
grabFrameParams.dwStartY = 0;
grabFrameParams.eGMode = NVFBCTO_SYS_SOURCEMODE_FULL;
grabFrameParams.pNVFBFrameGrabInfo = &frameGrabInfo;

NVFBRESULT result;
result = NVFBCToSys->NVFBCToSysGrabFrame(&grabFrameParams);
```

Please refer to NVFBC API Reference document for details regarding `NVFBCTO_SYS_GRAB_FRAME_PARAMS` struct.

By default, `NVFBCToSysGrabFrame()` is a blocking call, and returns once a new frame is available.

If the call is successful, `NVFBCToSysGrabFrame()` returns `NVFBCTO_SYS_SUCCESS`, information about the captured frame is returned in the `NVFBFrameGrabInfo` struct passed as `NVFBCTO_SYS_GRAB_FRAME_PARAMS::pNVFBFrameGrabInfo`, and the readback buffer obtained via the `NVFBCToSysSetup()` call contains the captured frame data. If a diffmap pointer was specified in `NVFBCToSysSetup()`, the diffmap buffer will contain a difference map, unless this is the first frame captured after the `NVFBCToSysSetup()` call, in which case the difference map will contain all bits set to '1'.

If there is an error, `NVFBCToSysGrabFrame()` returns one of the errors enumerated in `NVFBRESULT`, indicating that a frame was not successfully captured. This can occur if the return value is:

- ▶ `NVFBCTO_SYS_ERROR_PROTECTED_CONTENT`: Protected content is currently being displayed. See section 2.15.1 for more information on handling protected content.
- ▶ The NVFBC object must be re-created. See section 2.15.2 for a discussion of the factors that require this.

Please refer to the NVFBC API Reference for details about `NVFBRESULT` values.

### 2.6.2.1 Blocking and non-blocking frame grabs

The `NVFBC_TOSYS_GRAB_FRAME_PARAMS::dwFlags` parameter can be used to control whether NVFBC should perform a blocking frame grab or a non-blocking frame grab. Please refer to `NVFBC_TOSYS_GRAB_FLAGS` in the NVFBC API Reference document to know more about the supported values.

**Note:** under normal operation, Windows may update the display image on a head with exactly the same image that was previously displayed. In this case, a blocking call `NVFBCToSysGrabFrame()` will return a new frame with identical content to the previous one. Similarly, a non-blocking call to `NVFBCToSysGrabFrame()` will always return the latest frame, which may not have changed from the last time `NVFBCToSysGrabFrame()` was called. In both these cases, Difference Maps (when enabled) can be used to detect when the frame returned is identical to the previous one.

### 2.6.2.2 Scaling and cropping

The `NVFBC_TOSYS_GRAB_FRAME_PARAMS::eGMode` parameter specifies the grab mode for the frame capture, controlling cropping or scaling on the captured frame. The grab modes are mutually exclusive.

Please refer to `NVFBCToSysGrabMode` in the NVFBC API Reference document to know more about supporting scaling\cropping modes.

Scaling of the capture frame may be useful when remoting frames to a client that has a lower resolution than the local frame resolution. By downscaling at the point of capture, the amount of data compressed and transmitted to the remote client is reduced.

Cropping of the frame may be useful when supporting a “panning” mode on a remote client with lower resolution than the local frame, or to capture a specific application window’s output.

### 2.6.2.3 Difference Maps

The difference maps feature is available with `NVFBCToSys` and `NVFBCToDx9Vid` interfaces. Please refer to Section 2.10 for details.

## 2.6.3 Grabbing Mouse Separately with NVFBCToSys

Cursor Capture support is available across all NVFBC interfaces starting from GRID SDK 4.1 and associated GPU driver. Refer to Section 2.9 for details.

## 2.6.4 Releasing the NVFBCToSys object

After you have finished using `NVFBCToSys` you must release it to properly free the resources.

```
NVFBRESULT NVFBCToSysRelease();  
// Example code  
toSys->NVFBCToSysRelease();
```

## 2.7 CAPTURING TO CUDA DEVICE MEMORY

To capture uncompressed frames to CUDA mapped buffers, create an NVFBC object from the NVFBCcuda class by specifying `NVFBC_SHARED_CUDA` in the `NVFBC_CreateEx()` call. Please refer to NVFBCcuda Object definition in the NVFBC API Reference document.

```
NVFBCcuda *pNVFBCcuda = (NVFBCcuda*)
    pfnNVFBC_CreateEx(NVFBC_SHARED_CUDA, &maxDisplayWidth,
                    &maxDisplayHeight, NULL);
```

`NVFBC_SHARED_CUDA` is used to capture frames in 32-bit ARGB pixel format, one byte per channel.

### 2.7.1 Allocating a CUDA device buffer

NVFBCcuda requires the caller to allocate buffers to hold grabbed frames. Use NVFBCcuda's `NVFBCcudaGetMaxBufferSize()` method to determine the maximum-sized frame that NVFBC can grab, then use `cudaMalloc()` to allocate a buffer in the GPU's framebuffer to accommodate it.

Please refer to `NVFBCcudaGetMaxBufferSize()` in NVFBC API Reference document.

```
// Determine maximum size that NVFBC can return
DWORD maxBufferSize = pNVFBCcuda->NVFBCcudaGetMaxBufferSize();
...

// Use CUDA driver API to alloc memory on CUDA device for grabbed frame
CUdeviceptr buffer;
cuMemAlloc(&buffer, maxBufferSize);
...

// Or, using the CUDA runtime API:
void * buffer;

cudaMalloc(&buffer, maxBufferSize);
```

## 2.7.2 Grabbing frames with NVFBCuda

Grabbing a frame with NVFBCuda is a single step process – call `NVFBCudaGrabFrame()` to trigger a readback, supplying a previously allocated CUDA buffer. Please refer to `NVFBCudaGrabFrame` in the NVFBC API Reference document.

```
NVFBCRESULT NVFBCudaGrabFrame (NVFBC_CUDA_GRAB_FRAME_PARAMS *pParams)
// Example of usage:

NVFBCFrameGrabInfo frameGrabInfo;

NVFBC_CUDA_GRAB_FRAME_PARAMS grabParams = {0};
grabParams.dwVersion = NVFBC_CUDA_GRAB_FRAME_PARAMS_VER;
grabParams.pCUDADeviceBuffer = (void *)buffer;
grabParams.pNVFBCFrameGrabInfo = &frameGrabInfo;
grabParams.dwFlags = NVFBC_TOCUDA_NOFLAGS;

NVFBCRESULT result;
result = pNVFBCuda->NVFBCudaGrabFrame(&grabParams);
```

The input/output parameters to `NVFBCudaGrabFrame()` are described in the following sections. By default, `NVFBCudaGrabFrame()` is a blocking call, and returns once a new frame is available. If the call is successful, `NVFBCudaGrabFrame()` returns `NVFBC_SUCCESS`, information about the captured frame is returned in the `NVFBC_CUDA_GRAB_FRAME_PARAMS::pNVFBCFrameGrabInfo` structure, and the supplied buffer contains the captured frame data.

If there is an error, `NVFBCudaGrabFrame()` returns one of the errors enumerated in `NVFBCRESULT`, indicating that a frame was not successfully captured. This can occur if the return value is:

- ▶ `NVFBC_ERROR_PROTECTED_CONTENT`: Protected content is currently being displayed . See section 2.15.1 for more information on handling protected content.
- ▶ `NVFBC_ERROR_INVALIDATED_SESSION`: The NVFBC object must be re-created (`bMustRecreate` is `TRUE` in the frame grab info structure). See section 2.15.2 for a discussion of the factors that require this.

Please refer to the NVFBC API Reference for details about `NVFBCRESULT` values.

### 2.7.2.1 Blocking and non-blocking frame grabs

The `NVFBC_CUDA_GRAB_FRAME_PARAMS::dwFlags` parameter specifies miscellaneous control flags for the call. Please refer to `NVFBC_CUDA_FLAGS` in the NVFBC API Reference document for more details.

**Note:** Under normal operation, Windows may update the display image on a head with exactly the same image that was previously displayed. In this case, a blocking call `NVFBCudaGrabFrame()` will return a new frame with identical content to the previous one. Similarly, a non-blocking call to `NVFBCudaGrabFrame()` will always return the latest frame, which may not have changed from the last time `NVFBCudaGrabFrame()` was called.

### 2.7.2.2 Frame grab info structure

Information about the grabbed frame is returned in the `NVFBCFrameGrabInfo` structure passed as `NVFBC_CUDA_GRAB_FRAME_PARAMS::pNVFBCFrameGrabInfo`. Please refer to the NVFBC API Reference document for details regarding `NVFBCFrameGrabInfo`.

## 2.8 CAPTURING TO IDIRECT3DSURFACE9\* BUFFERS

To capture uncompressed frames to system memory, create an NVFBC object from the NVFBCToSys class by specifying:

```
CreateParams.dwInterfaceType = NVFBC_TO_DX9_VID;
```

Please refer to `NvFBCToDx9Vid` Object definition in the NVFBC API Reference document.

### 2.8.1 Setting up the NVFBCToDx9Vid object

Before frames can be grabbed, the `NvFBCToDx9Vid` object requires a setup call, `NvFBCToDx9VidSetUp()`, to specify the target capture mode and the required grab format. The `NvFBCToDx9VidSetUp()` method registers client provided d3d9 surfaces for use with NVFBC.

Please refer to the NVFBC API reference document for details regarding `NVFBC_TODX9VID_SETUP_PARAMS` struct.

```
NVFBCRESULT NvFBCToDx9VidSetUp(NVFBC_TODX9VID_SETUP_PARAMS *pParam);

// Example of usage:
NVFBCRESULT res = NVFBC_SUCCESS;
NVFBC_TODX9VID_SETUP_PARAMS setup = {0}NVFBC_TODX9VID_OUT_BUF
fbcOut[NBUFFERS] = {0};

//! Allocate surfaces
for (int nsurfout = 0; nsurfout < NBUFFERS; nsurfout++)
{
    //! Create a surface to pass to NVFBC
    hr = pD3DDev->CreateOffscreenPlainSurface(curWidth, curHeight,
        D3DFMT_A8R8G8B8, D3DPOOL_DEFAULT,
        &fbcOut[nsurfout].pPrimary, NULL);
    if (FAILED(hr))
    {
        fprintf(stderr, "Failed to allocate NVFBC output surface.\n");
        return E_FAIL;
    }
}

//! Configure the grabber, get grab output buffer handle.
setup.dwVersion = NVFBC_TODX9VID_SETUP_PARAMS_VER;
setup.bWithHWCursor = false;
setup.dwNumBuffers = NBUFFERS;
setup.eMode = NVFBC_TODX9VID_ARGB;
setup.ppBuffer = fbcOut;
setup.bWithHWCursor = true;
res = toDx9Vid->NvFBCToDx9VidSetUp(&setup);
```

If successful, `NVFBCToDx9VidSetup()` returns `NVFBC_SUCCESS`, and the object is now ready for frame grabbing. Otherwise, it returns one of the errors enumerated in `NVFBCRESULT`.

### 2.8.1.1 Capture mode

The `setupParams.eMode` parameter is a capture mode that specifies the pixel format in which frame captures will be returned. Please refer the NVFBC API reference for details regarding `NVFBCToDx9VidBufferFormat` enum.

### 2.8.1.2 Hardware cursor handling

The `setupParams.bWithHWCursor` parameter controls hardware cursor compositing: if specified as `TRUE`, any active hardware cursor is composited into read back frames, otherwise it is not. If a software cursor is active, this will be composited into the frame regardless of this parameter setting.

### 2.8.1.3 Readback buffers

The application should create `d3d9` surfaces of a supported pixel format, and pass them as an array using the parameter `NVFBC_TODX9VID_SETUP_PARAMS::ppBuffer`.

The NVFBC API will register these surfaces as target surfaces for holding the grabbed images. A maximum of 3 output surfaces can be registered with a given NVFBC session. Calling this API again with new surfaces will instruct NVFBC to invalidate previous configuration and register the new surfaces.

The application is responsible for deallocating the surfaces, after releasing the NVFBC session or invalidating the registration with NVFBC.

## 2.8.2 Grabbing frames with NVFBCToDx9Vid

To grab a frame with `NVFBCToDx9Vid`, call `NVFBCToDx9VidGrabFrame()`:

```
NVFBCRESULT NVFBCToDx9VidGrabFrame(NVFBC_TODX9VID_GRAB_FRAME_PARAMS
*pParam);

// Example of usage:
NVFBCFrameGrabInfo frameGrabInfo;
NVFBC_TODX9VID_GRAB_FRAME_PARAMS

grabFrameParams = {0};
grabFrameParams.dwVersion = NVFBC_TODX9VID_GRAB_FRAME_PARAMS_VER;
grabFrameParams.dwFlags = NVFBC_TODX9VID_NOFLAGS;
grabFrameParams.eGMode = NVFBC_TOSYS_SOURCEMODE_FULL;
grabFrameParams.dwBufferIdx = i;
grabFrameParams.pNVFBCFrameGrabInfo = &frameGrabInfo;

NVFBCRESULT result;
result = toDx9Vid->NVFBCToDx9VidGrabFrame(&grabFrameParams);
```

Please refer to NVFBC API Reference document for details regarding NVFBC\_TODX9VID\_GRAB\_FRAME\_PARAMS struct.

By default, NVFBCToDx9VidGrabFrame () is a blocking call, and returns once a new frame is available.

If the call is successful, NVFBCToDx9VidGrabFrame () returns NVFBC\_SUCCESS, information about the captured frame is returned in the NVFBCFrameGrabInfo struct passed as NVFBC\_TODX9VID\_GRAB\_FRAME\_PARAMS::pNVFBCFrameGrabInfo, and one of the readback buffer registered via the NVFBCToDx9VidSetup () call contains the captured frame data.

If there is an error, NVFBCToSysGrabFrame () returns one of the errors enumerated in NVFBCRESULT, indicating that a frame was not successfully captured. This can occur if the return value is:

- ▶ NVFBC\_ERROR\_PROTECTED\_CONTENT: Protected content is currently being displayed. See section 2.15.1 for more information on handling protected content.
- ▶ The NVFBC object must be re-created. Please refer section 2.15.2 for a discussion of the factors that require this.

Please refer to the NVFBC API Reference for details about NVFBCRESULT values.

### 2.8.2.1 Blocking and non-blocking frame grabs

The NVFBC\_TODX9VID\_GRAB\_FRAME\_PARAMS::dwFlags parameter can be used to control whether NVFBC should perform a blocking frame grab or a non-blocking frame grab. Please refer to NVFBC\_TODX9VID\_GRAB\_FLAGS in the NVFBC API Reference document to know more about the supported values.

**Note:** under normal operation, Windows may update the display image on a head with the exact same image that was previously displayed. In this case, a blocking call NVFBCToDx9VidGrabFrame () will return a new frame with identical content to the previous one. Similarly, a non-blocking call to NVFBCToDx9VidGrabFrame () will always return the latest frame, which may not have changed from the last time NVFBCToDx9VidGrabFrame () was called. In both these cases, Difference Maps (when enabled) can be used to detect when the frame returned is identical to the previous one.

### 2.8.2.2 Scaling and cropping

The `NVFBC_TO_DX9VID_GRAB_FRAME_PARAMS::eGMode` parameter specifies the grab mode for the frame capture, controlling cropping or scaling on the captured frame. The grab modes are mutually exclusive.

Please refer to `NVFBCToDx9VidGrabMode` in the NVFBC API Reference document to know more about supporting scaling\cropping modes.

Scaling of the capture frame may be useful when remoting frames to a client that has a lower resolution than the local frame resolution. By downscaling at the point of capture, the amount of data compressed and transmitted to the remote client is reduced.

Cropping of the frame may be useful when supporting a “panning” mode on a remote client with lower resolution than the local frame, or to capture a specific application window’s output.

### 2.8.3 Releasing the NVFBCToDx9Vid object

After you have finished using `NVFBCToSys` you must release it to properly free the resources.

```
// Example code
NVFBCRESULT NVFBCToDx9VidRelease();
toDx9Vid->NVFBCToDx9VidRelease();
```

## 2.9 CAPTURING HW CURSOR ON SEPARATE THREAD

To enable grabbing the HW cursor separately, the client must set the flag `bEnableSeparateCursorCapture` in the respective NVFBC interface setup parameters.

For example, for `NVFBCToSys`, set `NVFBC_TOSYS_SETUP_PARAMS::bEnableMouseGrab` while calling `NvFBCToSysSetup()`.

If this flag is set, NVFBC will return a valid event handle in `hCursorCaptureEvent` member of the setup parameters. For example, `NVFBC_TOSYS_SETUP_PARAMS::hCursorCaptureEvent`

Every time NVFBC captures an update to the cursor, this event will be signaled. The client should spawn a thread to wait on this event. The thread should wake up when the event is signalled and read back the cursor data.

Below is a sample code snippet to grab cursor glyph using NVFBCToSys:

Please refer to NVFBC\_CURSOR\_CAPTURE\_PARAMS in NVFBC API Reference document for details.

```

//! Example Code
NVFBC_TOSYS_SETUP_PARAMS fbcSysSetupParams = {0};
//! Common configuration code here
//!...
//! Set up separate HW cursor grab
fbcSysSetupParams.bEnableMouseGrab = true;
status = NVFBCToSys->NVFBCToSysSetUp(&fbcSysSetupParams);
hMouseEventHandle = fbcSysSetupParams.hCursorCaptureEvent;

NVFBC_CURSOR_CAPTURE_PARAMS pCursorCaptureParams;
pMouseGrabParams.dwVersion = NVFBC_CURSOR_CAPTURE_PARAMS_VER;
while(1)
{
    WaitForSingleObject(handle ,INFINITE); //handle returned from
//!NVFBCToSysSetUp call
    ToSys->NVFBCToSysCursorCapture(&pCursorCaptureParams);
    if(pMouseGrabParams.bIsHwCursor)
    {
        out = base + _itoa(FrameID, frameNo, 10) + ".bmp";;
        SaveARGB(out.c_str(), (BYTE*) pCursorCaptureParams.pBits,
pCursorCaptureParams.dwWidth, pCursorCaptureParams.dwHeight);
        temp++;
    }
}

```

## 2.10 DIFFERENCE MAPS

Difference maps are supported for NVFBCToSys and NVFBCToDX9Vid interfaces.

The difference map format is a byte array, where each byte represents a block of the pixel region on the screen (in row-major order). If the byte is non-zero then some pixels have changed in that region. For resolutions that aren't a multiple of 128 in either direction, the resolution is rounded up to the next multiple of 128.

In order to get an accurate reconstruction of the grabbed images, the client application must apply each difference map since the last reference image. Discarding one or more difference maps may lead to corruption in reconstructed images. If the client application needs to discard a grabbed image, it should still merge the difference map with the previously captured difference map. Since difference maps are bit-arrays, the cost of condensing multiple difference maps into one buffer is very low: it can be achieved by OR-ing two 128-bit arrays.

## 2.10.1 Configuring Difference Map

NVFBC Capture SDK 6.1 adds support for generating difference maps with block size of 16x16, 32x32, 64x64 apart from legacy 128x128 blocksize. The client should call `NvFBC_GetStatusEx()` to determine if the driver supports configuring pixel block size for difference maps. `NvFBCStatusEx::bSupportConfigurableDiffMap` is set if 16x16, 32x32, 64x64 block sizes are supported.

Any supported block size can be requested by setting the parameter `NVFBC_TODX9VID_SETUP_PARAMS::eDiffMapBlockSize` with one of the enum in `NVFBC_DX9VID_DIFFMAP_BLOCKSIZE`. This enum must be typecasted to `NvU32` before assigning. Eg:

```
NVFBC_TODX9VID_SETUP_PARAMS NvFBCDX9SetupParams = { 0 };
. . . . .
NvFBCDX9SetupParams.bDiffMap = TRUE;
NvFBCDX9SetupParams.eDiffMapBlockSize =
                                (NvU32) NVFBC_DX9VID_DIFFMAP_BLOCKSIZE_16X16;
NvFBCDX9SetupParams.dwDiffMapBuffSize = DIFF_MAP_BUF_SIZE;
NvFBCDX9SetupParams.ppDiffMap = (void **) &g_pDiffMap;
result = NvFBCDX9->NvFBCToDx9VidSetUp(&NvFBCDX9SetupParams);
. . . . .
```

**Note:** The client must call `NvFBC_GetStatusEx()` to check for configuring difference map block size. `bSupportConfigurableDiffMap` is set if 16x16, 32x32, and 64x64 difference map is supported. If the client requests any of these block sizes in setup parameters for an unsupported driver, NVFBC will ignore the request and return 128x128 difference map.

## 2.11 IMAGE AREA CLASSIFICATION MAPS

NVIDIA Capture SDK 7.0 introduces a new feature for classifying areas of images that may benefit from being encoded at a higher quality. This feature is referred to as NVFBC Image Area Classification, and its output is referred to as a Classification Map. This output can be directly passed to NVENC, where it is referred to as the Emphasis Map. This feature is supported by `NvFBCToSys` and `NvFBCToDx9Vid` interfaces. It can be enabled along with the NVFBC Difference map feature.

The classification map format is a byte array, where each byte represents a 16x16 block of the pixel region on the screen (in row-major order). The value of the byte can be from 0 to 5. A value of 0 indicates the corresponding pixel block is a flat region - that is, a low frequency region. A non-zero value indicates the strength of high frequency content in the pixel block, with 5 indicating the highest strength.

The following is an example of setting up the NVFBC Image Area Classification feature.

```
NVFBC_TODX9VID_SETUP_PARAMS NvFBCDX9SetupParams = { 0 };

. . . . .

NvFBCDX9SetupParams.bClassificationMap= TRUE;

NvFBCDX9SetupParams.dwClassificationMapStampWidth = 16;

NvFBCDX9SetupParams.dwClassificationMapStampHeight = 16;

NvFBCDX9SetupParams.dwClassificationMapBuffSize =

                                NVFBC_TODX9VID_MAX_CLASSIFICATION_MAP_SIZE;

NvFBCDX9SetupParams.ppClassificationMap=(void**) &g_pClassificationMap;

result = NvFBCDX9->NvFBCToDx9VidSetUp(&NvFBCDX9SetupParams));

. . . . .
```

**Note:** The client must call `NVFBC_GetStatusEx()` to check if the driver supports the Image Area Classification feature. The bit field `bSupportImageClassification` will be set if the image area classification feature is supported.

## 2.11.1 Configuring Classification Map

The client can configure the classification map output by choosing stamp size. Stamp is any valid rectangular shape that can be built by a unit of 16x16 pixel block. By selecting a stamp size for this feature, NVFBC ensures that the High Frequency strength output is uniform across each 16x16 pixel block within a stamp. Refer to the whitepaper [NvFBC\\_Image\\_Area\\_Classification\\_WhitePaper.pdf](#) from NVIDIA Capture SDK documents directory for more details on how stamp size affects output.

The classification map output is always 16x16 reduced, irrespective of the stamp configuration the client chooses.

**Note:** Classification Map buffer output is always 16x16 reduced, and each byte corresponds to a 16x16 pixel block of the grabbed frame. Stamp dimension does not alter this mapping.

NVFBC accepts only a valid stamp size as input. A stamp size is valid only if following criteria are satisfied.

- ▶ Stamp width and height dimension must be a multiple of 16.

- ▶ Minimum stamp height and width is 16 pixels.
- ▶ Maximum stamp height and width is 256 pixels.

An invalid stamp size will result in `NVFBC_ERROR_INVALID_PARAM` returned from the NVFBC session setup.

## 2.12 10 BIT AND HDR CAPTURE SUPPORT

### 2.12.1 NVFBC 10 bit capture support

NVIDIA Capture SDK 6.0 adds support for ARGB10 output format to the following interfaces: `NvFBCToSys`, `NvFBCToDx9Vid` and `NvFBCToCuda`.

To request 10 bit Capture, the client should use the 10 bit capture format enum from the corresponding interface. Eg: For `NvFBCToSys`, the client should use `NVFBC_TOSYS_ARGB10`.

Any 8 bit to 10 bit format conversion required will be taken care by the driver.

```
NVFBC_TOSYS_SETUP_PARAMS fbcSysSetupParams = {0};

fbcSysSetupParams.eMode = NVFBC_TOSYS_ARGB10;
. . . . .

result = nvfbcToSys->NvFBCToSysSetUp(&fbcSysSetupParams);
. . . . .
```

### 2.12.2 NVFBC 10 bit HDR capture support

NVIDIA Capture SDK 6.0 adds support for capturing in HDR format if the display is configured for HDR, and the content is rendered in HDR.

To request HDR capture, the client should set the "bHDRRequest" flag in NVFBC setup parameters. A new flag, `NvFBCToSysFrameGrabInfo::bIsHDR`, should be used to check if the current captured frame is in HDR. `NvFBCToSysFrameGrabInfo::bIsHDR` will be set to 1 only if client requests HDR capture and NVFBC is able to capture in HDR format.

```
NVFBC_TOSYS_SETUP_PARAMS fbcSysSetupParams = {0};

fbcSysSetupParams.eMode = NVFBC_TOSYS_ARGB10;

fbcSysSetupParams.bHDRRequest = TRUE;

. . . . .

result = nvfbcToSys->NvFBCToSysSetUp(&fbcSysSetupParams);
```

```

. . . . .
fbcSysGrabParams.pNvFBCFrameGrabInfo = &grabInfo;
if (grabInfo.bIsHDR)
{
    // captured content is HDR
}

```

**Note:** 10 bit HDR HEVC encode support is available only for Pascal GPUs, using NVENC API. NVFBCToHWEnc interface does not have support for 10bit or HDR capture.

## 2.13 USING NVENC FOR COMPRESSING CAPTURED OUTPUT

The NVFBCCuda interface delivers output images on a client-supplied cuDevicePtr whereas the NvFBCToDx9Vid interface delivers output images on a client-supplied IDirect3DSurface9\* (or IDirect3DSurface9Ex\*) object. Both objects are directly usable as inputs to the NVENC API.

The NvFBCCudaNvEnc sample application demonstrates how to pass desktop images captured using NvFBCCuda to NVENC for video compression.

The NvFBCToDx9NvEnc sample application demonstrates the same for the NvFBCToDX9Vid interface.

## 2.14 FACTORS REQUIRING NVFBC OBJECT RE-CREATION

Under the following circumstances, NVFBC objects must be destroyed and re-created in order to continue grabbing frames. This is indicated by

NvFBCFrameGrabInfo::MustRecreate set to TRUE in the NvFBCFrameGrabInfo structure or NVFBC\_ERROR\_SESSION\_INVALIDATED error code returned by a Grab call.

- ▶ The system transitions through an S3 (sleep) or S4 (hibernate) power state – for example, on a notebook platform, the user closes and later re-opens the notebook.
- ▶ Display topology is changed during an active NVFBC capture session.

Display capabilities are changed in a manner that changes the maximum display resolution, while an NVFBC capture session is running. Threading considerations

NVFBC is designed for use in multi-threaded applications, to allow for parallelism in handling readback operations on different heads, and in CPU-based post-processing of pixel data returned from NVFBC.

However, the API requires that all NVFBC API calls made on a given NVFBC object should be made from the thread that created the object. If an application uses an NVFBC object in different threads, each of those threads may have NVFBC API calls outstanding at the same time. Exceptions to this are as follows:

- ▶ In case a thread running an NVFBC session exits abnormally, the application should reset the directx9 device that was being used for NVFBC interaction, as the abnormal exit may leave the directx9 device context in an unstable state.
- ▶ The requirement is relaxed in case the client is using separate HW mouse cursor capture API in conjunction with NVFBCToSys. In this case, it is permitted to use NVFBCToSysCaptureMouse() and NVFBCToSysGrabFrame() on separate threads.

## 2.15 HANDLING ERRORS FROM NVFBC GRAB API

When NVFBC Grab succeeds, the API returns a status code `NVFBC_SUCCESS`. In case of failure, the API can return status codes depending upon the error. The status codes are documented in NVFBC API reference. In addition,

`NVFBCFrameGrabInfo::dwDriverInternalError` holds more information about the failure. This is intended to be used as diagnostic information while investigating failures. If the API succeeds, this code should be ignored.

The table below outlines some values that can be actionable for the client application:

Value	Meaning
0xFBCB0001	Non-fatal. Grab was called while a resolution change or display topology change was in progress
0xFBCB0002	Non-fatal. Invalid grab flags, retry with a valid value for grab flags. Current request was treated as if no flags were set.
0xFBCB0003	Non-fatal. No screen update for 1 second after the capture session was created, output is black.
0xFBCE0003	Non-fatal. Invalid parameters, retry with correct parameters.
0xFBCE0004	Fatal. Invalid sequence of API calls or Capture session is in invalid state. Release capture session and create new session.
0xFBCE0027	Non-fatal. Invalid cropping rect, retry with valid cropping rect based on current and maximum display dimensions.
0xFBCE0028	Non-fatal. Invalid scaling target rect, retry with valid target rect.
0xFBCE0044	Fatal. NVFBC feature was disabled since the last Grab(). Release capture session.

**Table 3: NVFBC Grab API Diagnostic codes**

### 2.15.1 Handling protected content

Playback of protected content such as DVD or BluRay disks typically requires an encrypted, secured path to the physical display output device. To prevent violation of protected content license terms, NVFBC will not capture frames from the GPU whenever a protected content session is active.

NVFBC indicates the presence of protected content by returning `NVFBC_ERROR_PROTECTED_CONTENT` from calls to `NVFBC_GrabFrame()`, and no frame data is returned.

While protected content is active, applications should fall back to non-accelerated, standard Windows APIs to capture the desktop without the protected content, in order

to continue providing visual output to the user. In parallel with this, NVFB API frame grabs should be attempted periodically to determine when the protected content session has ended, and accelerated frame grabbing is once again possible. Figure 4 summarizes the suggested program flow:

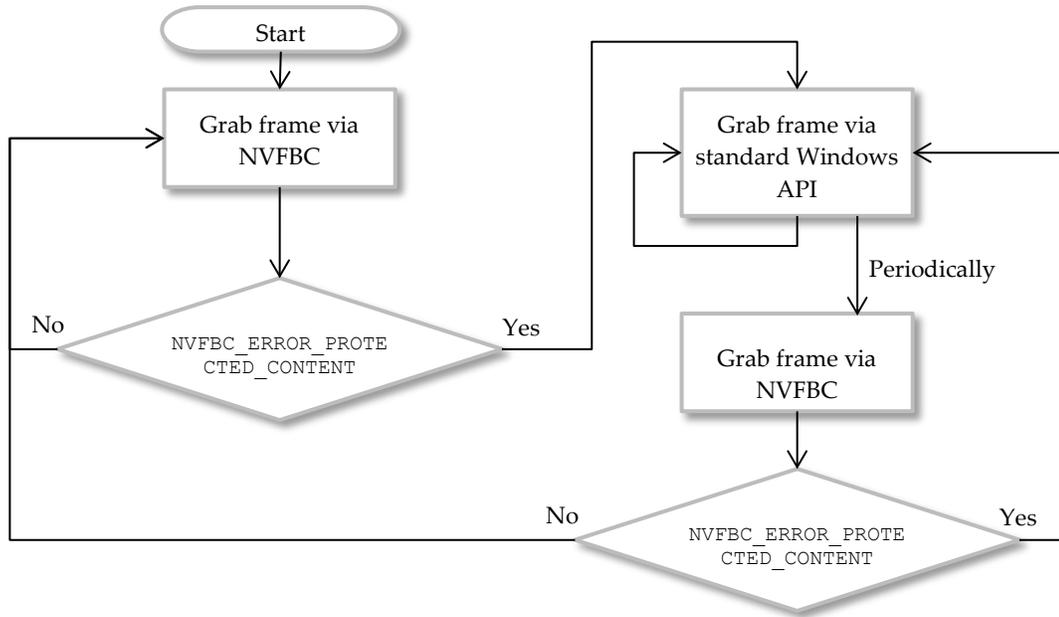

Figure 4 Handling protected content

## 2.15.2 Handling an Invalidated Session

If the error code `NVFBC_ERROR_INVALIDATED_SESSION` is returned when attempting a frame grab, the user must re-create the NVFBC session by:

- ▶ Destroying allocated buffers and closing event handles.
- ▶ Releasing NVFBC by calling the `Release()` API of the corresponding interface.
- ▶ If possible, releasing the DX9 device that was passed to NVFBC, and creating a new device.
- ▶ Following the NVFBC initialization steps again.

```
pNVFBCToSys->NVFBCToSysRelease();  
  
pNVFBCToSys = (NVFBCToSys*) pfnNVFBC_Create (NVFBC_TO_SYS, &maxWidth,  
&maxHeight);  
  
//! Setup the grab and encode  
  
NVFBCRESULT result;  
...  
result = pNVFBCToSys->NVFBCToSysSetUp(&setupParams);
```

# Chapter 3. DEPLOYING A GRID-ENABLED APPLICATION

This chapter provides guidance on shipping a GRID-enabled application.

## 3.1 DEPLOYMENT ON WINDOWS

Deploying an NVFBC-enabled application with GeForce, Quadro, and Tesla GPUs on Windows platforms requires that you deploy a Microsoft DirectX redistributable runtime along with your application, and execute an install-time applet to set NVIDIA Capture SDK's required registry settings.

### 3.1.1 Microsoft DirectX redistributable runtime

The NVIDIA Capture SDK DLLs are linked with version 33 of the Microsoft DirectX runtime. As this version may not be present on an end user's platform, you should include the Microsoft redistributable end-user runtime with your application. The redistributable can be downloaded from here:

<http://www.microsoft.com/download/en/details.aspx?displaylang=en&id=8109>

### 3.1.2 DLL installation

When shipping an NVFBC-enabled application, you do not need to include the NVFBC DLLs with your shipping application, as they are included in NVIDIA driver releases after 320.00.

DLL	Install Path	Notes
NVFBC.DLL	For 32Bit OS: %systemroot%\system32 For 64Bit OS: %systemroot%\syswow64	Application should load the correct version [32bit\64bit] of the DLLs based on the OS and application's target architecture from the paths listed here. Application should not package these DLLs with their installers, as they will be installed along with NVIDIA drivers.
NVFBC64.DLL	For 64Bit OS only. %systemroot%\system32	

**Table 4 NVIDIA Capture SDK DLL Path Names, Install Locations**

The DLL locations in the NVIDIA Capture SDK Toolkit are shown in Table 24 above.

### 3.1.3 Registry settings

The NVIDIA Capture SDK's NVFBC component requires some registry settings to be present on the system to operate correctly. Enable and disable of these registry settings is abstracted into a simple executable, `NVFBCEnable.exe`, which should be shipped with your application install package and executed during application installation.

- ▶ To enable NVFBC registry settings, execute: `NVFBCEnable -enable`.
- ▶ To disable NVFBC registry settings, execute: `NVFBCEnable -disable`.
- ▶ To check status of NVFBC on your system, execute: `NVFBCEnable -checkstatus`

`NVFBCEnable` is provided in `...\ in the GRID toolkit.`

After changing the registry settings, this tool will trigger a reload of the driver to ensure that the settings have taken effect.

Please note that this tool will need to be run on a system before using it to run the SDK samples or test an application using NVFBC.

### 3.1.4 Enabling generation of logs

NVFBC supports generating textual and ETW logs of varying verbosity. Logging can be enabled by setting the following registry entries:

#### NVFBC:

```
[HKEY_LOCAL_MACHINE\SOFTWARE\NVIDIA Corporation\GRID]
```

```
"NVFBCLog"=dword:000000xy
```

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\NVIDIA Corporation\GRID]
```

```
"NVFBCLog"=dword:000000xy
```

Permissible values for x:

- 0- No logging
- 1- Log errors only
- 2- Log errors and names of APIs called
- 3- Log errors, names of APIs and parameters passed to APIs
- 4- Log everything

Permissible values for y:

- 0- Log ETW events only
- 1- Log to console + ETW events
- 2- Log ETW events + text file on disk, in “%PROGRAMDATA%\NVIDIA Corporation\NvFBC” directory.

#### ETW Provider GUID:

```
{ 0x3dacf5bb, 0xe6b7, 0x46cf, { 0xa3, 0xbb, 0x6d, 0x37, 0x80, 0x53, 0x62, 0xf0 } }
```

In case of any problems encountered while using the NVFBC APIs, the client can collect the logs by setting these registry settings.

## Notice

ALL NVIDIA DESIGN SPECIFICATIONS, REFERENCE BOARDS, FILES, DRAWINGS, DIAGNOSTICS, LISTS, AND OTHER DOCUMENTS (TOGETHER AND SEPARATELY, "MATERIALS") ARE BEING PROVIDED "AS IS." NVIDIA MAKES NO WARRANTIES, EXPRESSED, IMPLIED, STATUTORY, OR OTHERWISE WITH RESPECT TO THE MATERIALS, AND EXPRESSLY DISCLAIMS ALL IMPLIED WARRANTIES OF NONINFRINGEMENT, MERCHANTABILITY, AND FITNESS FOR A PARTICULAR PURPOSE.

Information furnished is believed to be accurate and reliable. However, NVIDIA Corporation assumes no responsibility for the consequences of use of such information or for any infringement of patents or other rights of third parties that may result from its use. No license is granted by implication of otherwise under any patent rights of NVIDIA Corporation. Specifications mentioned in this publication are subject to change without notice. This publication supersedes and replaces all other information previously supplied. NVIDIA Corporation products are not authorized as critical components in life support devices or systems without express written approval of NVIDIA Corporation.
