NVIDIA GPUs at Facebook

Context

NVIDIA GPUs at Facebook

Why the need for a dedicated efficiency effort

Large shared GPU pool for training

- Mainly Pascal and Volta GPUs, 8 per server
- CUDA 9 (soon 10)
 - Mix of CUDA libraries (cuDNN, cuBLAS, ...) & custom kernels

Various users across several teams

- Their own distinct use cases, changes over time
- Computer vision, speech, translation and many more
- Many machine learning experts, not as many GPU experts

Caffe2 and PyTorch 1.0 in containers

facebook Artificial Intelligence

Enable GPU experts to improve efficiency across teams with minimal workload context

You can't improve what you can't measure

Efficient Algorithms

This is us

Efficient Resource Utilization - A Complete Picture

Many layers of inefficiency The top part could fill another talk We will focus on the portion of time when GPUs have been allocated to a job

Zooming in on NVIDIA GPU Utilization

nvidia-smi: GPU 100% utilized SM Efficiency: GPU ~1% utilized

What does utilization mean?

High-level utilization metric is coarse (GPU in use?) Doesn't show how many SMs / functional units in use

A kernel with a single thread running continuously will get 100% GPU utilization

Even if it only uses 0.1% of available GPU resources!

H/W Event: SM Active Cycles:

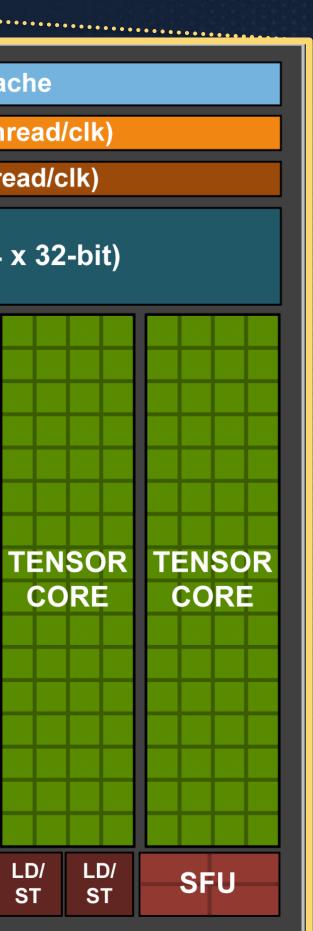

Cycles where SM had > 0 active warps

Metric: SM Efficiency: SM Active Cycles / SM Elapsed Cycles

Zooming in on SM Utilization

What does utilization mean?

SM Efficiency does not tell the whole story

Single active warp will not utilize SM to anywhere near its potential

Active Warps:

Number of warps in-flight on an SM concurrently (0-64)

Achieved Occupancy:

Active Warps / Active Cycles

Even more detail:

*_fu_utilization - Per-functional unit utilizationInstructions per cycle (IPC) FLOPS / peak FLOPS

CUPTI – the CUDA Profiler Tools Interface

Dynamic library for writing profiling and tracing tools

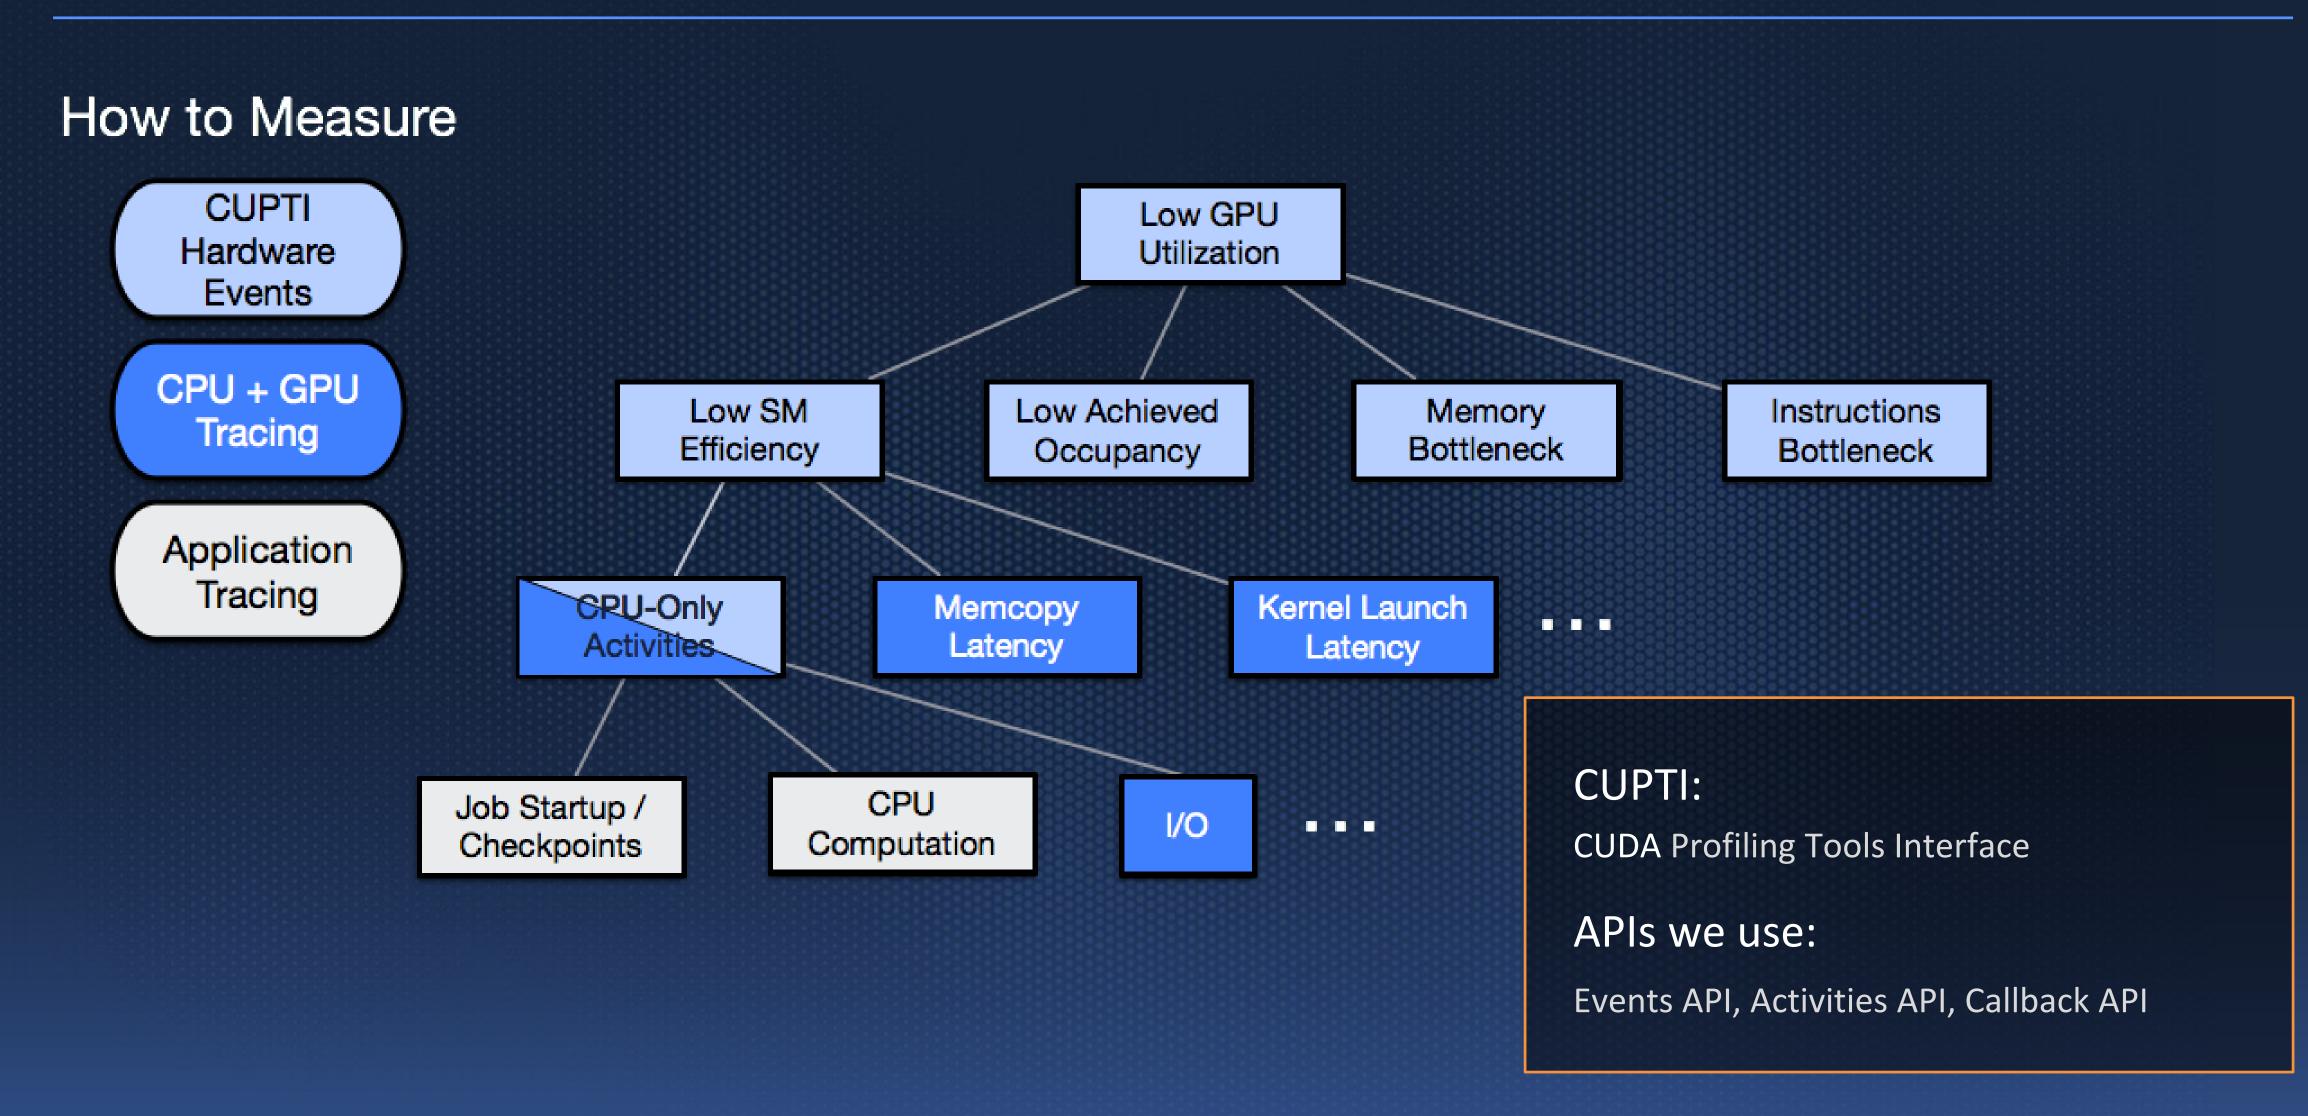

Provides multiple APIs:

- **Activity API:** GPU tracing, e.g. kernel launches, memcopies
- **Callback API:** Driver and library API tracing
- **Event API:** GPU events, e.g. cycles, instructions, active warps
- **Metric API**: Predefined metrics, e.g. SM Efficiency, Achieved Occupancy
- **Profiler API:** Kernel replays, range profiling

Library (libcupti) must be linked into application to be profiled

Fleetwide On-Demand Training

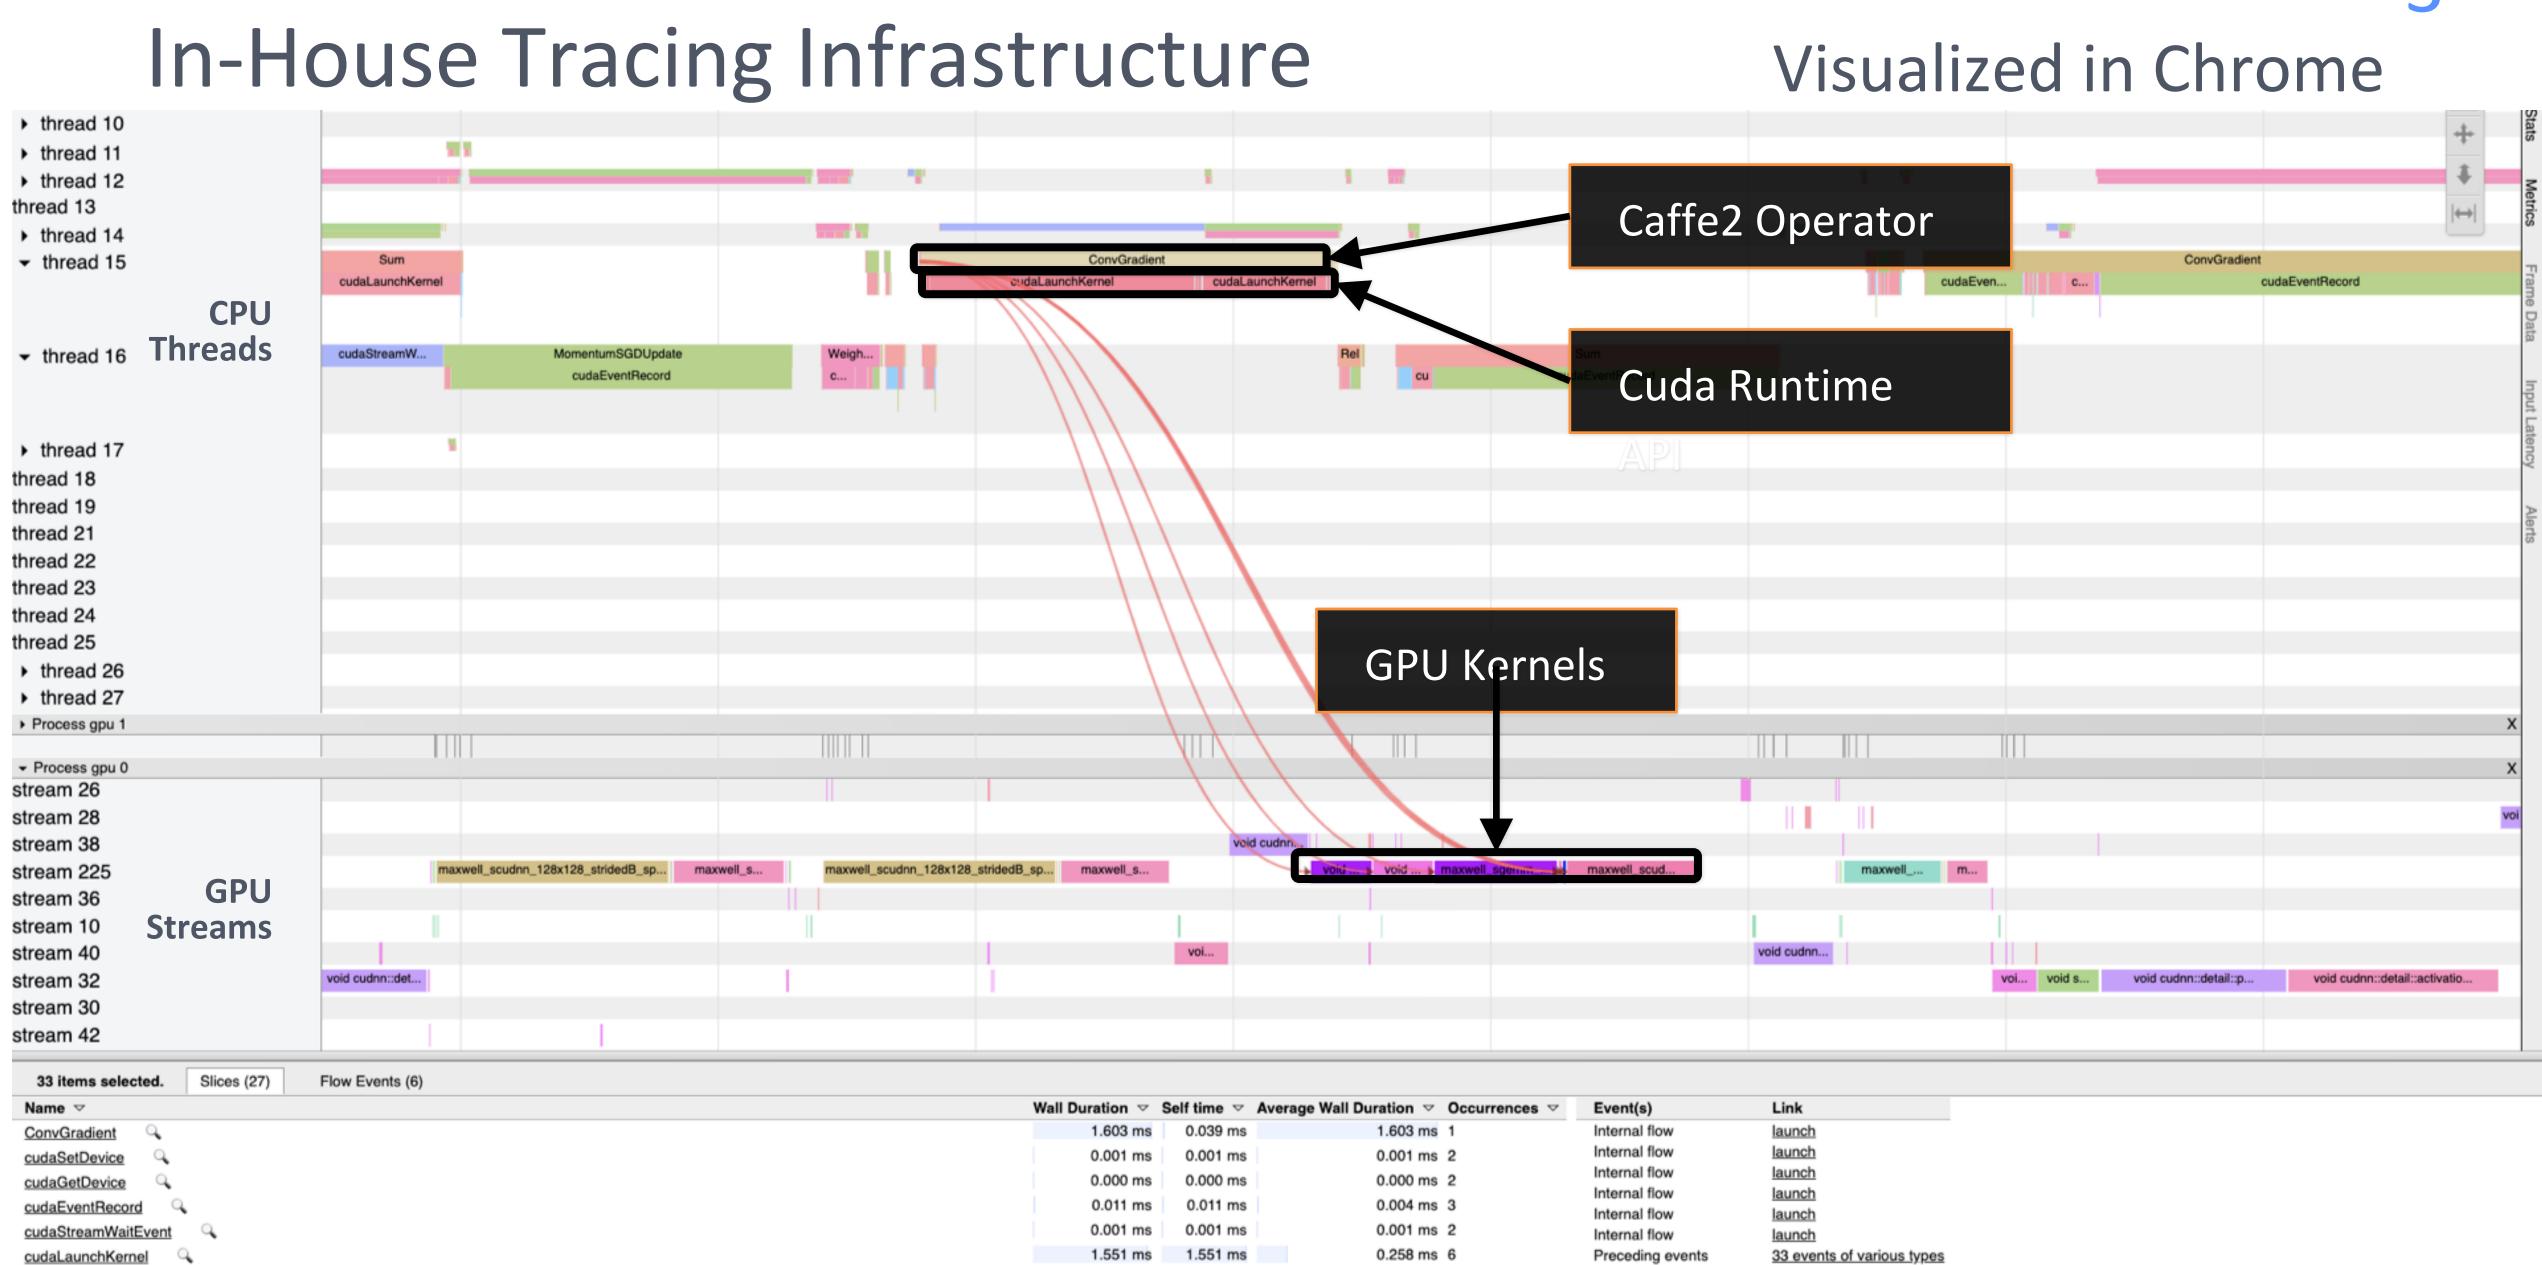

Always available tracing at the push of a button

We use our own tracing library today for the following reasons:

- Always available **on-demand** (no workload config or build mode)
- Available in **production** (at very low overhead)
- **Integrated** with job management UI and other relevant perf tools
- **Browser-based** (including visualization)

We use CUPTI Activities API to implement on-demand tracing for production workflows. In the future, we hope to expand our use of Nsight Systems.

Libgpumon

Profiling and tracing lihrary

Detailed utilization metrics and tracing on-demand for all production workflows

Application

OS

Telemetry and Profiling Takeaways

Visibility, top-down, full coverage

Collect metrics deep and wide

- Hierarchical top-down breakdown
- Detailed utilization metrics
- Break down by team, user, package, workflow, GPU kernels etc.

Systematically address low utilization with on-demand tracing

- Nsight Systems and CUPTI Activity API for CPU-GPU interactions
- Application level tracing for big picture

Target frequently used GPU kernels with nvprof and Nsight Compute

What to target: Use periodic tracing to rank kernels across fleet

Best experience when all these integrate smoothly

Commonly observed reasons for poor utilization and how to address them

A One-Minute Primer to Caffe2 and PyTorch

The vast majority of GPUs at FB are used for training machine learning models using Caffe2 or PyTorch

Caffe2 and PyTorch are open source deep learning platforms that facilitate expression, training, and inference of neural network models

In Caffe2 models are expressed by defining a graph for the neural network whose nodes are operators

PyTorch supports eager mode in which the graph is expressed implicitly through control flow in an imperative program In practice the graph can usually be automatically generated to facilitate optimizations and tracing support similar to Caffe2

API and Platform Design Choices that Improve Performance

Caffe2 platform support

For translating loops into kernel code with proper block sizes; helps improve SM utilization and occupancy

Dependency-tracking system for operators

Performs memory copies into and out of GPU memory generally only when required

Automatic fusion of operators

Prevents unnecessary copies and kernel invocations

CUDA's similarity to C++

Reduces the barrier of entry for writing GPU code

Causes of Performance Issues in GPU Code

A case of mistaken assumptions

GPUs differ significantly from CPUs

- Much higher number of execution units
- Data-parallel code and execution
- Lower single-thread performance
- Accelerator managed by the CPU

Each difference requires an adaptation in code patterns for good performance

Most new GPU programmers are experienced CPU programmers

They often use common CPU practices and coding patterns, which may not work well on the GPU

Patterns of GPU Misuse

Most GPU performance issues result from a Blind Spot or mistaken assumptions about key GPU architectural aspects As a result, the programmer writes Anti-Pattern code that performs poorly Often, a simple Solution is available to a whole class of problems

Issue 1: CPU to GPU Communication Latency

So close, yet so far away

Blind Spot: Overhead of kernel launches and cudaMemcpy is relatively high

And GPUs are not designed to allow executing a large number of cudaMemcpy calls concurrently

Anti-Pattern: Code that transforms GPU data using CPU loops containing fine-grained cudaMemcpy calls

blocks of GPU threads

Solution: Rewrite these operations as GPU kernels that transform the data using

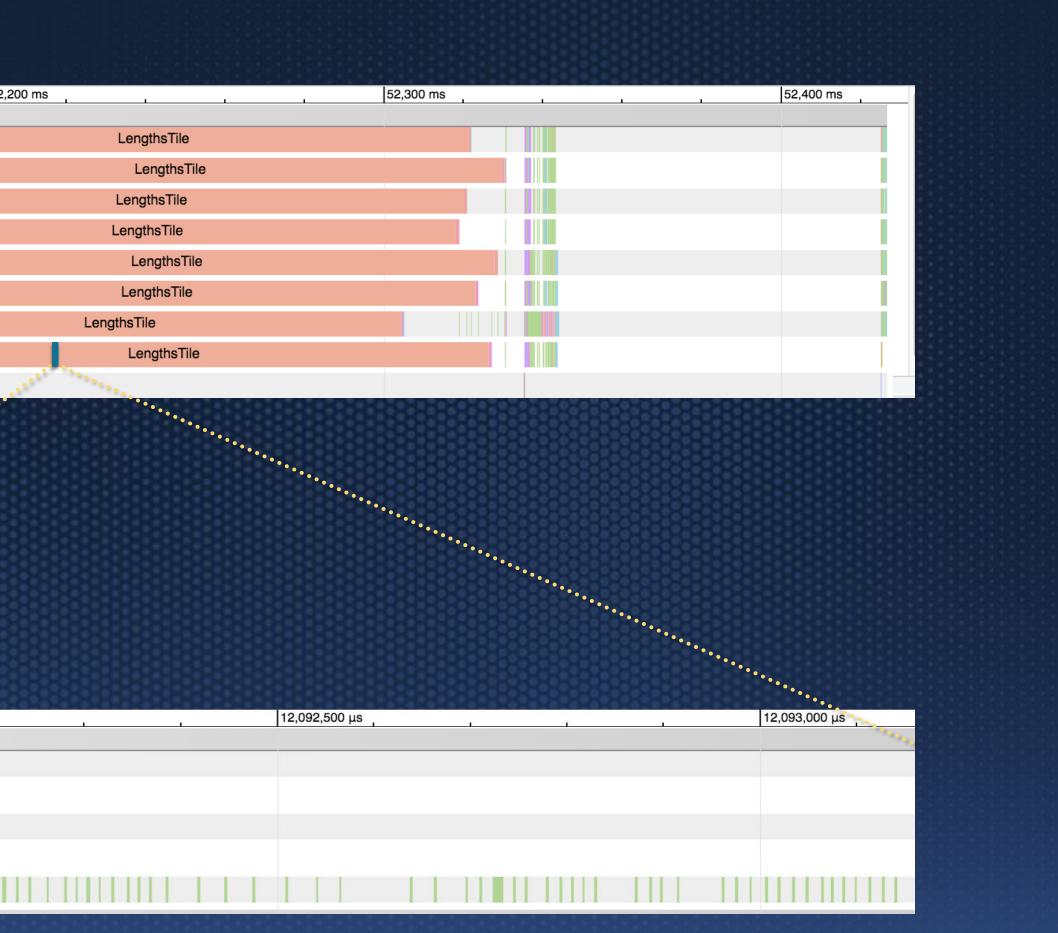

Example: The Case of the 14k cudaMemcpy Calls

200x op speedup, 3.5x workflow speedup

Issue 2: Bottlenecks at the CPU Cause High GPU Idle Time

Feeding the beast

Blind Spot: Peak throughput is much higher on GPU than on CPU

Anti-Pattern: Code that performs expensive data transformations on the CPU, causing GPU to go idle for extended time

that take advantage of the available concurrency

execution to help feed the GPU more effectively

- **Solution 1:** Do as much as possible of the expensive work on the GPU with kernels
- Solution 2: Run more threads on the CPU to concurrently prepare work for GPU

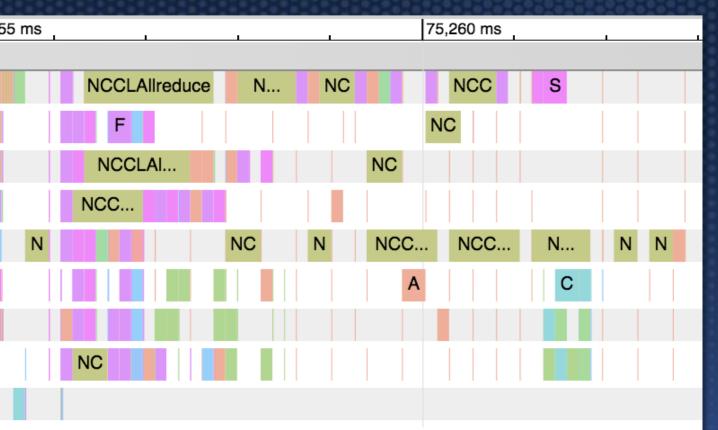

Example: The Case of the Well-Utilized CPU Threads

... and poorly utilized GPUs

A workflow used 8 CPU threads to manage the 8 GPUs on the server CPU timeline showed good thread utilization, GPU timeline showed gaps improved overall throughput by 40%

	75,250 ms	1 1	75,255

140494282684160			

- Increasing the number of threads on the CPU (from 8 to 64) to concurrently prepare more GPU work

Issue 3: Improper Grain Size per GPU Thread

The more the merrier

Blind Spot: On the CPU, the work per thread needs to be substantial (e.g. to absorb context-switch overhead), but GPUs switch between warps of threads very efficiently, so keeping grain size very low is fine

Anti-Pattern: GPU code with too much work per thread artificially limits concurrency, yielding low block count and SM efficiency

Solution: Rewrite kernels to expose more concurrency and increase number of blocks per kernel

Issue 4: Improper Memory Access Patterns

affect achieved memory bandwidth by more than an order of magnitude

different memory segments or individual threads copy large chunks of memory

utilize bandwidth effectively

- **Blind Spot:** GPU memory data access patterns between threads in the same warp can
- Anti-Pattern: Code with inefficient memory access patterns, where threads access
- **Solution:** Rewrite kernels to structure memory access patterns in the proper way to

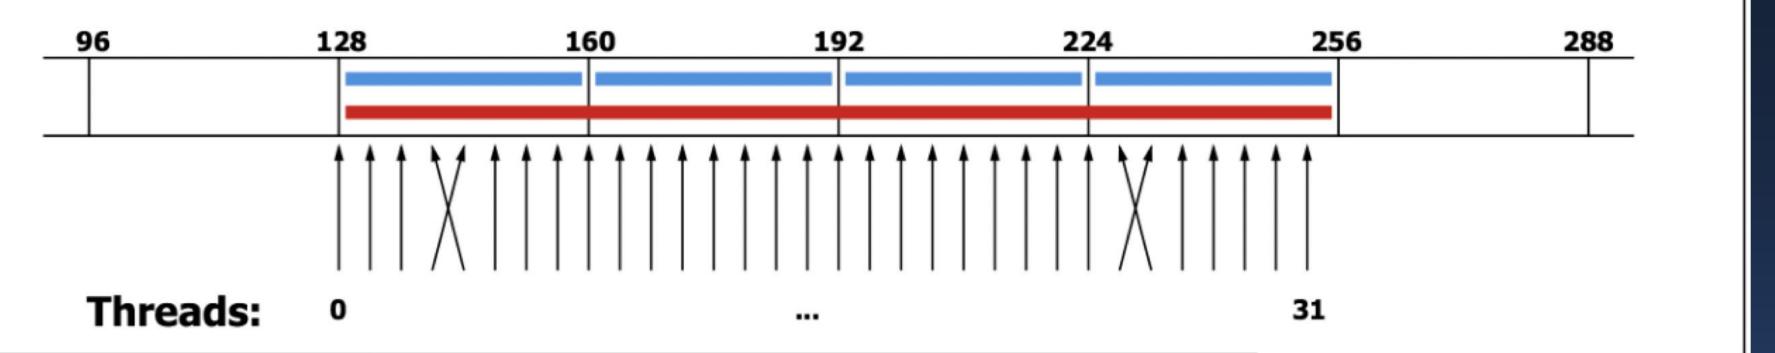

Proper GPU Global Memory Access Patterns

Threads access addresses in the same segments

Each thread fetches one word (fine grain)

Aligned accesses (sequential/non-sequential)

Addresses:

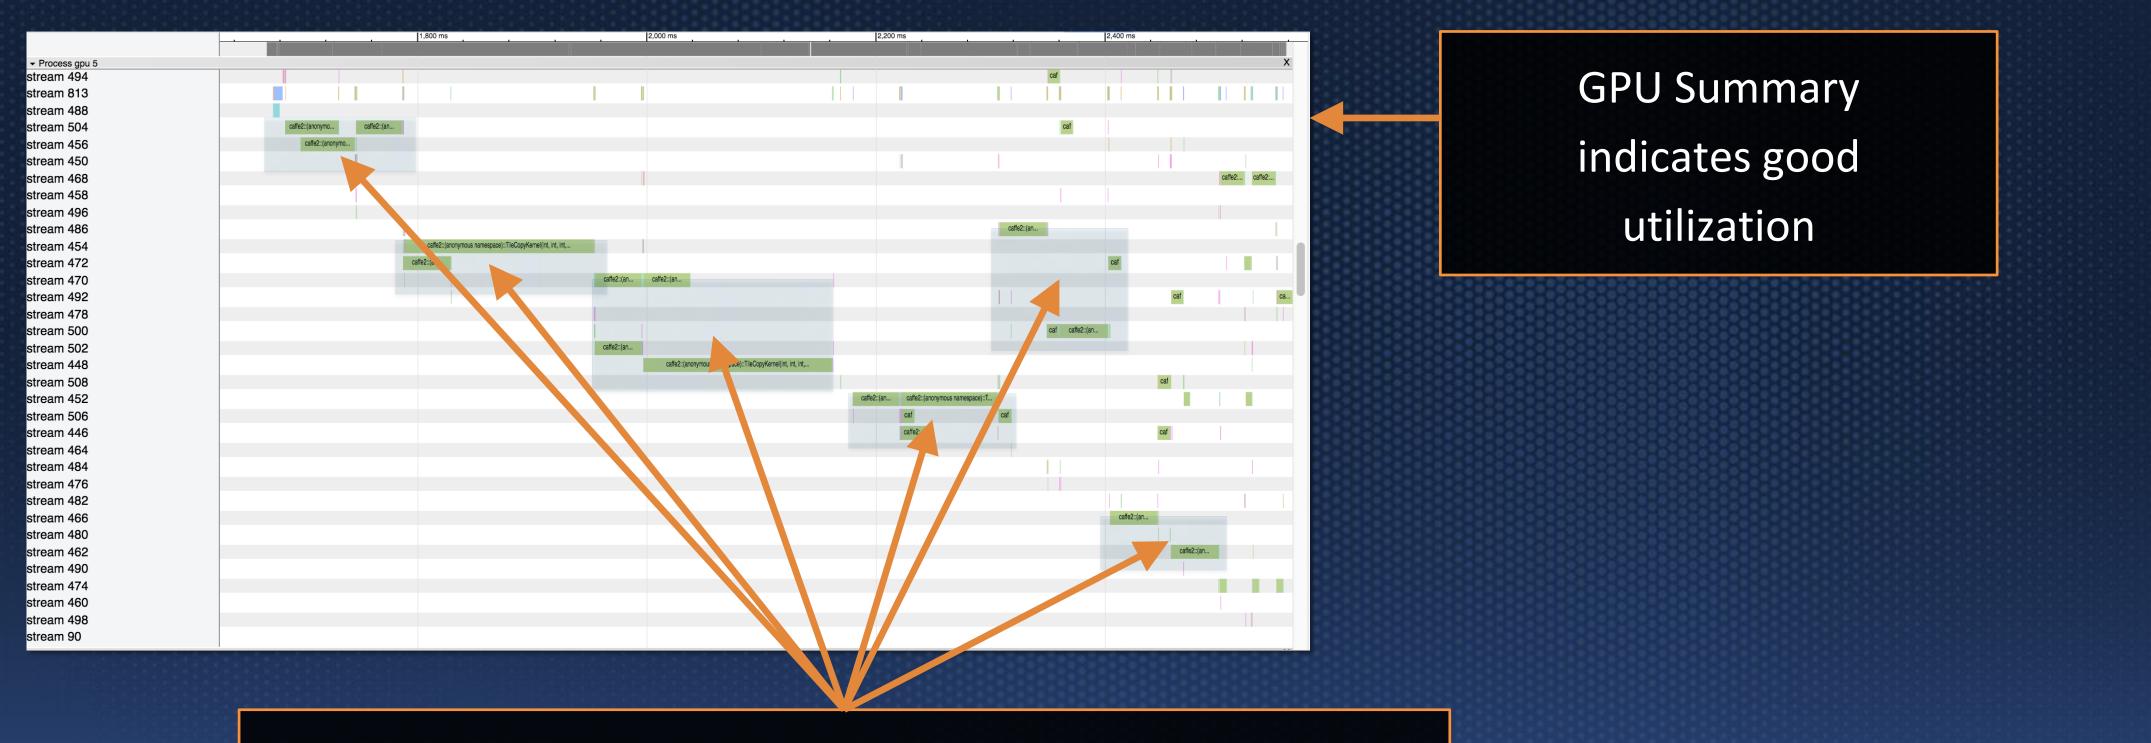

facebook Artificial Intelligence

Source: CUDA Programming Guide

Example: Increase Concurrency and Improve Memory Access Pattern

A timeline for a workflow showed 95% of GPU active time in one operator that performed a data transformation

95% of active time spent executing one kernel type

Example: Increase Concurrency and Improve Memory Access Pattern

Two birds with one stone

A timeline for a workflow showed 95% of GPU active time in one operator that performed a data transformation

Each thread in the kernel block was issuing a memcpy inside GPU global memory to replicate a large portion of the input tensor

We rewrote the kernel code so each thread would write a single value of the output tensor memcpy(output_ptr, input_ptr, inner_dim * item_size);

output_data[index] = input_data[row * inner_dim + col];

3x speedup in operator and workflow

Issue 5: Insufficient Concurrency

When a GPU for your workload is overkill

Blind Spot: Modern GPUs contain thousands of arithmetic units, so code must expose that much concurrency for proper utilization

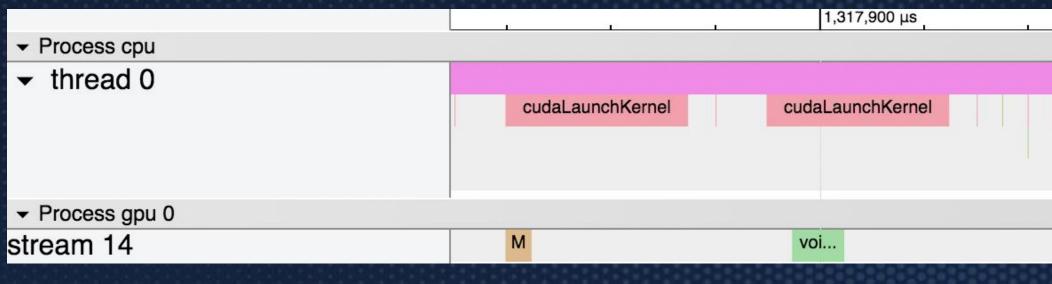

Anti-Pattern: Code that runs a few kernel blocks at a time with only a small fraction of SMs utilized

Solution: If the problem inherently has low concurrency, consider running on CPU instead

Example: Too Little Work

than to run it

	1,317,920 μs		1,317,940 µs	L

Optimization Takeaways

Platform abstractions allow our workflow developers to make use of GPUs and help with some performance aspects

Timeline tracing is the first tool you should use for identifying bottlenecks in parallel workflows To become a better GPU programmer, understand the key differences between GPU and CPU

architectures

- Very high parallelism requires high concurrency and efficiently feeding work from CPU
- Accelerator minimize CPU to GPU communication
- Zero-cost "context switch" don't be afraid to keep grain size very low
- Access patterns learn the optimal access patterns for the various memory/cache types on the GPU

Don't reinvent the wheel - use optimized libraries like cuDNN whenever possible

Thank you for watching

GPU Timeline Analysis

NVIDIA Nsight Systems

Understanding the work*flow*

cases

- Collects both CPU and GPU traces
- API for adding application-level trace events
- Great at highlighting system-wide bottlenecks

In addition, we use CUPTI Activities API directly

- NVIDIA's tools are built on top of CUPTI APIs
- Allows greater flexibility
- Derive metrics on-the-fly, aggregate per-kernel stats etc

A tracing tool such as NSight Systems is what we use to investigate low utilization

Use off-the-shelf tracing tools or use CUPTI APIs to build your own

Data-Driven Efficiency

%GPU Hours and Average Active Warps by Workflow

Goodput is not easily measurable workload and context dependent From images processed to user engagement rates Cost is standardized and measurable E.g. GPU hours

Poor utilization = waste of expensive resource TODO: clarify Focus on improving utilization - lower cost for the same goodput

facebook Artificial Intelligence

 $Utilization = \frac{Resources_{Used}}{Resources_{Available}}$

Used resources is measurable in context independent manner

Various levels of system metrics From GPU hours to FLOPs / instructions

Available resources is measurable Available GPU hours, peak FLOPs / instructions

Data-Driven Efficiency

Contributors to Low GPU Utilization
