ATOM: Accelerating Therapeutics for Opportunities in Medicine

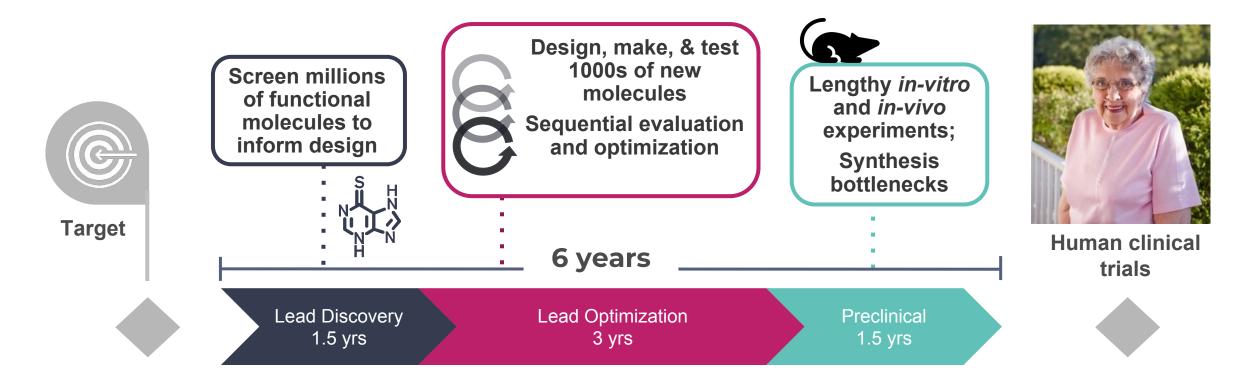

ATOM

What is ATOM?

- Approach: An open public-private partnership
 - Lead with computation supported by targeted experiments
 - Data-sharing to build models using everyone's data
 - Build an open-source framework of tools and capabilities
- Status:
 - Shared collaboration space at Mission Bay, SF
 - 25 FTE's engaged across the partners
 - R&D started March 2018
 - In the process of engaging new partners

Current drug discovery: long, costly, high failure Is there a better way to get medicines to patients?

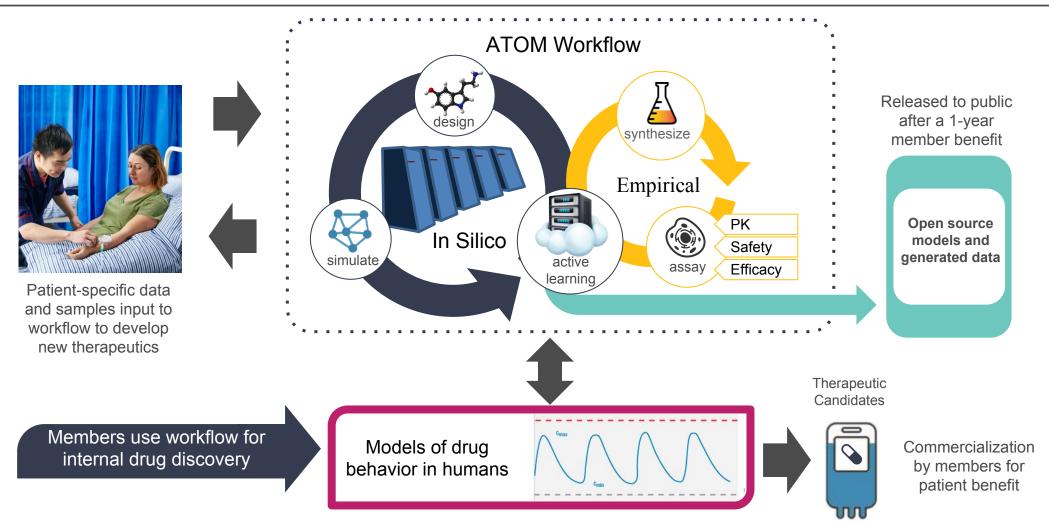

- 33% of total cost of medicine development
- Clinical success only ~12%, indicating poor translation in patients

Source: http://www.nature.com/nrd/journal/v9/n3/pdf/nrd3078.pdf

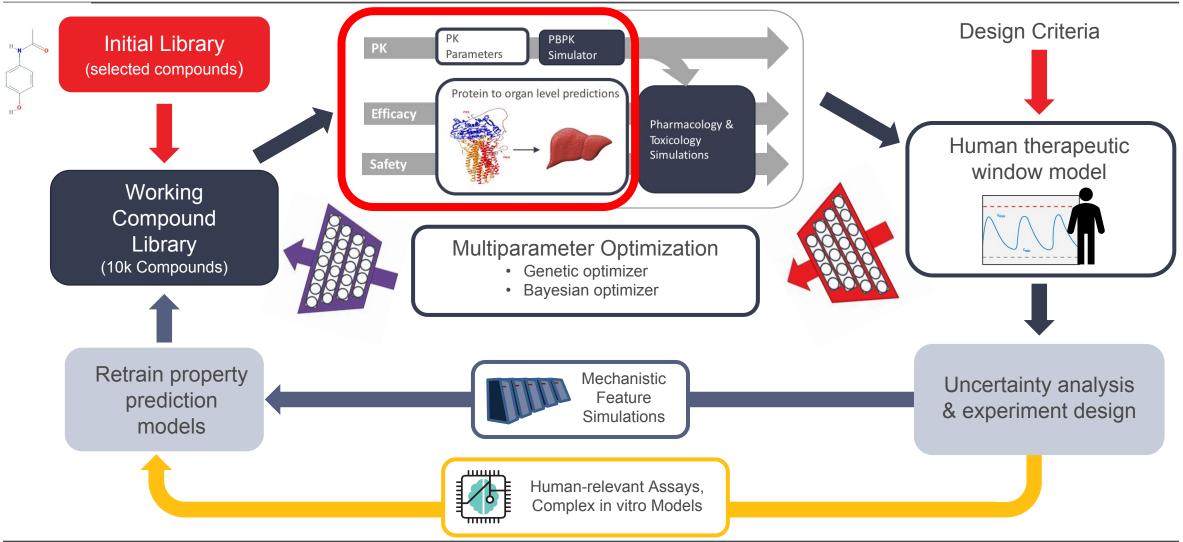

ATOM

Accelerated drug discovery concept

Vision of ATOM workflow in practice

Top-level view of the ATOM molecular design platform

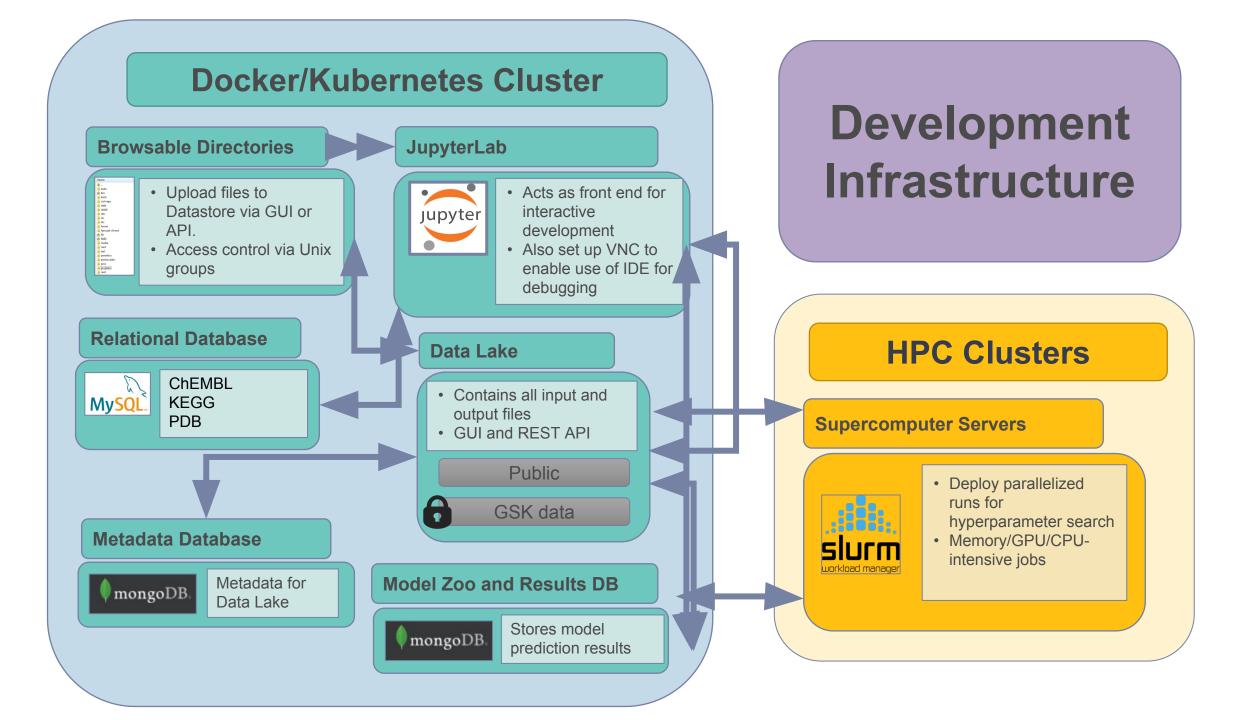

Software framework is being released as open source

Roadmap

- Infrastructure and Architecture what GPUs are we using?
- Data-Driven Modeling Pipeline what have we built?
- Experiments what have we been able to do?
- Future work where are we going from here?

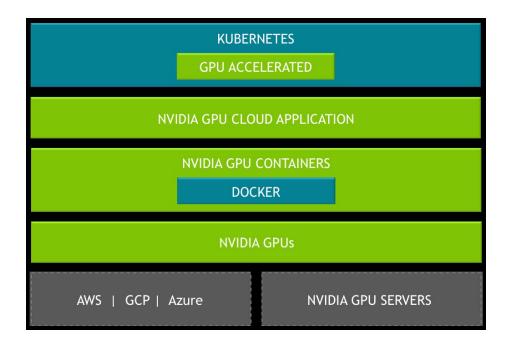

Roadmap

- Infrastructure and Architecture what GPUs are we using?
- Data-Driven Modeling Pipeline what have we built?
- Experiments what have we been able to do?
- Future work where are we going from here?

Kubernetes allocates GPU resources on our development server

- Our development server has 4 GPU nodes with 4 Titan XPs in each node
- 1 data server (cephid), 1 login/head node
- Kubernetes is an open source container orchestrator
- Manages containerized workloads and services
- Use it to orchestrate allocation of GPUs, CPUs, and memory
- Handles Role-Based Access Control

LLNL HPC Software Specs and Computer Architecture

- Nodes: 164
- Cores/Node: 36
- Total Cores: 5,904
- Memory/Node: 256
- Total Memory: 41,984 GB
- GPU Architecture: NVIDIA Tesla P100 GPUs
- Total GPUs: 326

• GPUs per compute node: 2

Data services are a necessity

- Data services are required to organize:
 - Raw data
 - Curated datasets
 - Model-ready datasets
 - Train/test/validation split of datasets
 - Serialized models
 - Performance results
 - Simulation output
- These data types vary in size, format, and level of organization/complexity

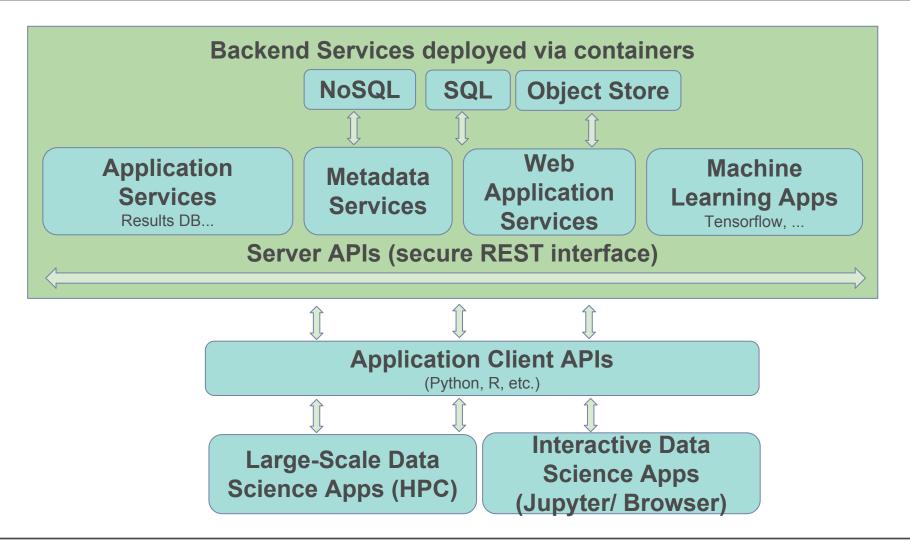

Have a variety of services to handle our needs

- Data Lake
 - In-house object store service
 - Allows for association of complex metadata with any type of file
 - Can access via GUI and REST API
- mongoDB
 - Used as backend for Data Lake metadata
 - Used as backend for Model Zoo metadata
 - Used for Results DB
- MySQL
 - Many public datasets are available in SQL format

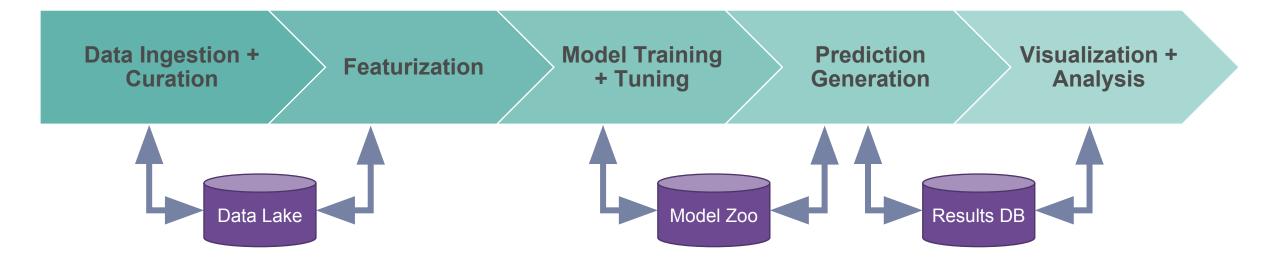

Overall structure of data services

Roadmap

- Infrastructure and Architecture what GPUs are we using?
- Data-Driven Modeling Pipeline what have we built?
- Experiments what have we been able to do?
- Future work where are we going from here?

End-to-End Data-Driven Modeling Pipeline Enables portability of models and reproducibility of results

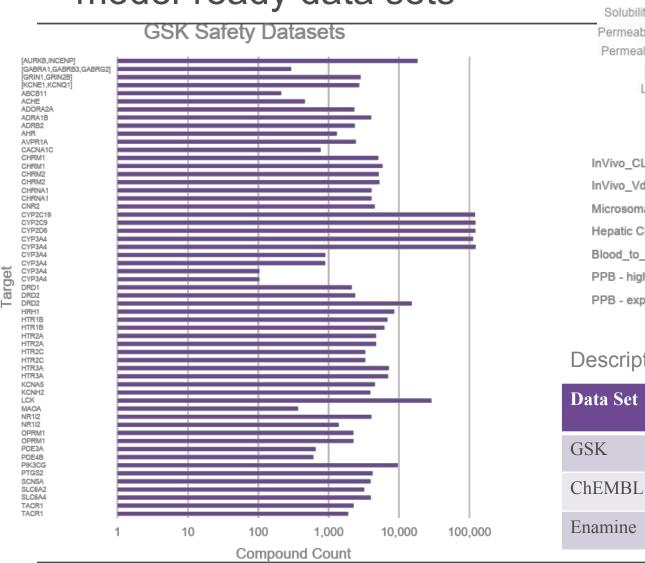

- Raw pharma data consists of 300 GB of a variety of bioassay and animal toxicology data on ~2 million compounds from GSK
- Proprietary or sensitive data must only be stored on approved servers
- Data may need to remain sequestered from other members

ATOM has curated ~150 model-ready data sets

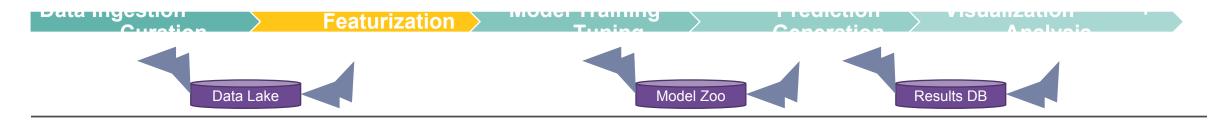

GSK Pharmacokinetic Datasets

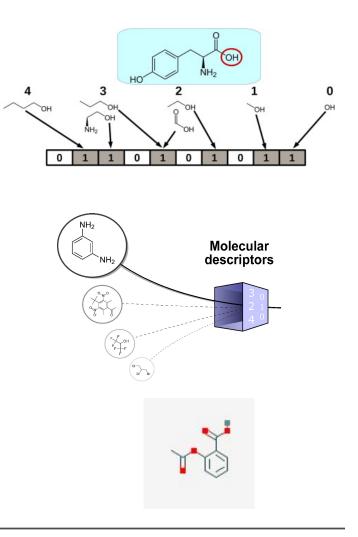

1.6M

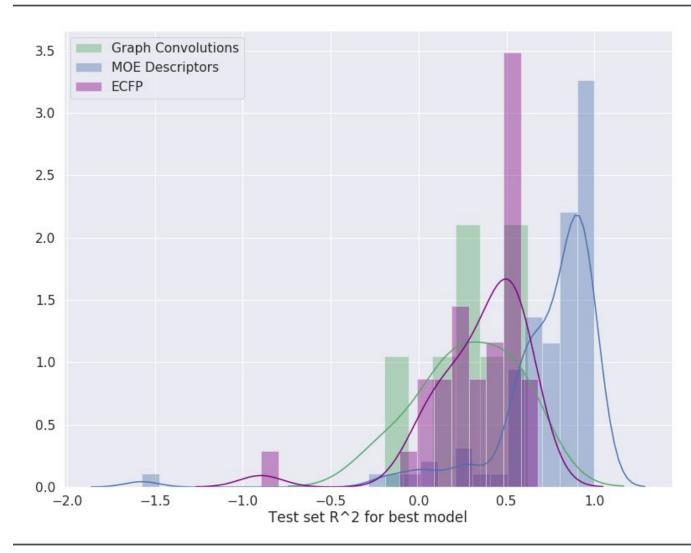

680M

- Support loading datasets from either Data Lake or filesystem
- Support a variety of feature types
 - Extended Connectivity Fingerprint
 - Graph-based features
 - Molecular descriptor-based features (MOE, DRAGON7, rdkit)
 - Autoencoder-based features (MolVAE)
 - Allow for custom featurizer classes
- Split dataset based on structure to avoid bias

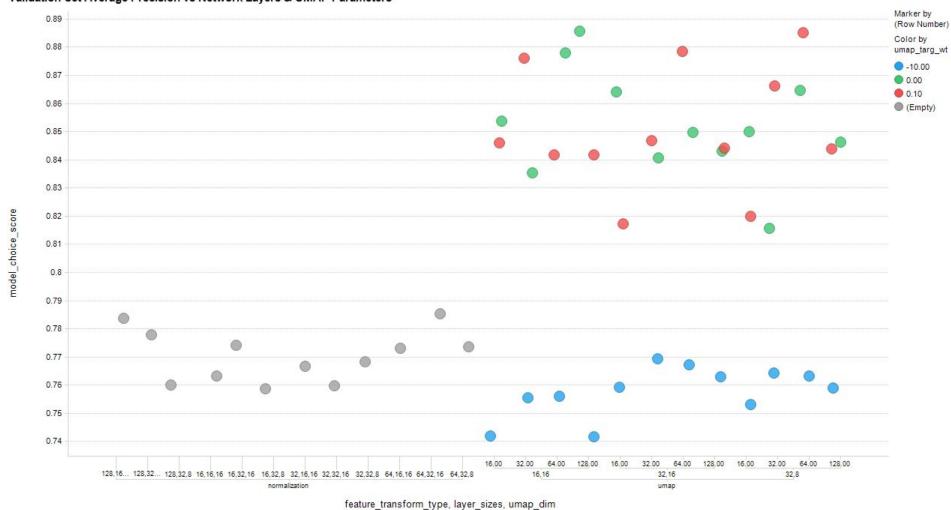

Featurization is key

- We have found that the best-performing feature type varies by dataset
- In general chemical descriptors out-perform other feature types
- Graph Convolutions occasionally outperform others

Dimensionality reduction can improve performance

Validation Set Average Precision vs Network Layers & UMAP Parameters

ATOM

 Have built a train/tune/predict framework to create high-quality models

learn

deepchem

- Currently support:
 - sklearn models
 - deepchem models (wrapper for TensorFlow)
 - Allow for custom model classes
- Tune models using the validation set and perform k-fold cross validation

O PyTorch

Hyperparameter optimization

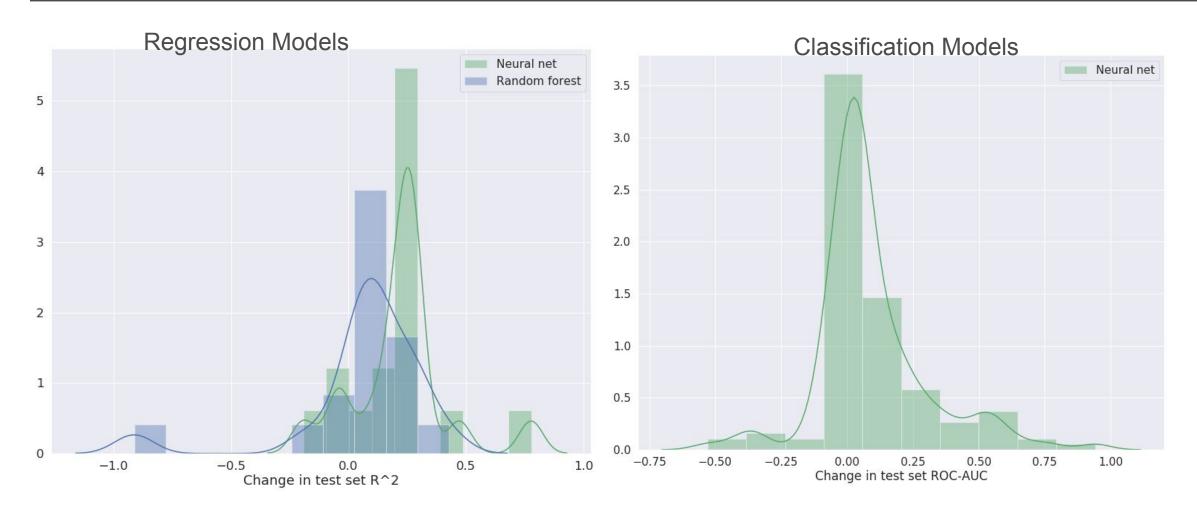

Support distributed hyperparameter search for dataset/feature/model combinations

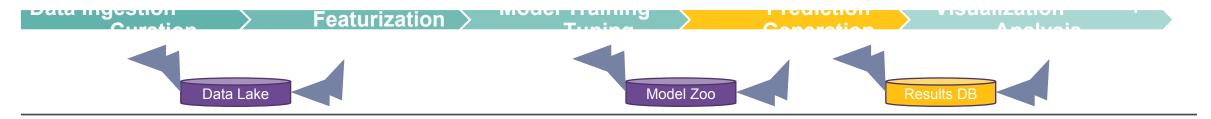

- Support linear grid, logistic grid, random, and user-specified steps
- Currently does not support optimization
- Specify input with JSON file or command line
- Generates all possible combinations of hyperparams, accounting for model type
- Groups neural net architecture combinations

Hyperparameter search improves model accuracy for both regression and classification models

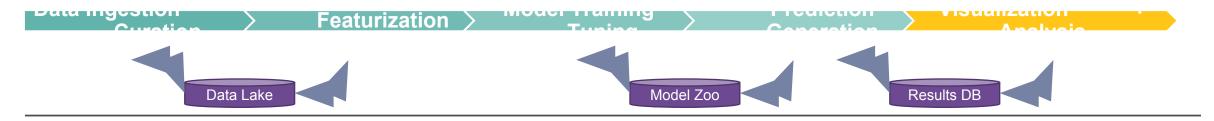

- Our models predict
 - Binding activation/inhibition values for safety-relevant proteins
 - Pharmacokinetic parameters for input into QSP models
 - Also working on hybrid ML/Molecular Dynamics models
- Calculate model-based uncertainty quantification metrics
- If ground truth provided, calculate a variety of prediction accuracy metrics
- All predictions and results saved to Results Database or file system based on user preference

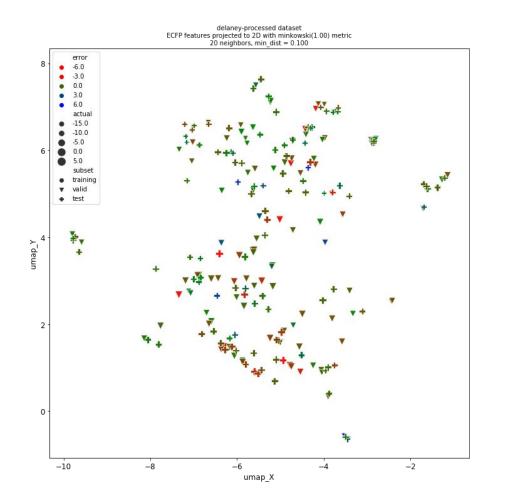

- Model Portability is key for:
 - Releasing to the public
 - Sending to partners for testing with internal data
 - Incorporating into Lead Optimization Pipeline for *de novo* compound generation
- Serialized models are saved to model zoo with detailed metadata
- Support complex queries for model selection
- One command generates queries from dictionary or JSON file, searches model zoo, and loads matching models

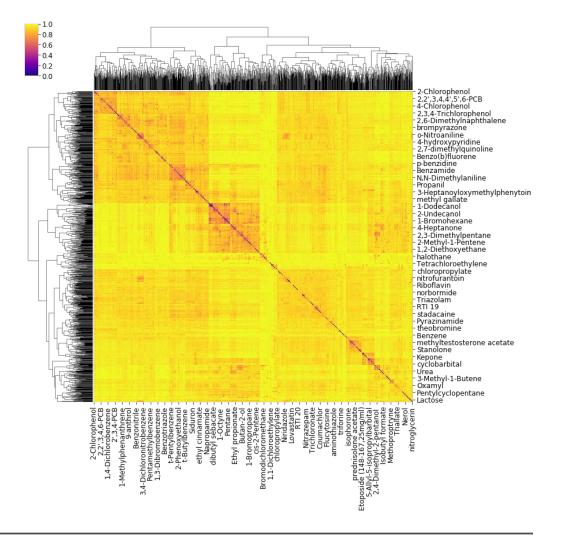

- Visualizations enable validation and evaluation of results
- Support variety of visualizations and also allow for custom functions
- Examples:
 - Predicted vs actual values
 - Learning curve
 - ROC curve/ precision vs. recall curve
 - 2-D projection of numeric features using UMAP

- Chemical diversity analysis is crucial for analyzing domain of applicability, bias in dataset splitting, and novelty of *de novo* compounds
- Support a number of input feature types, distance metrics, and a variety of clustering, analysis, and plotting methods

Roadmap

- Infrastructure and Architecture what GPUs are we using?
- Data-Driven Modeling Pipeline what have we built?
- Experiments what have we been able to do?
- Future work where are we going from here?

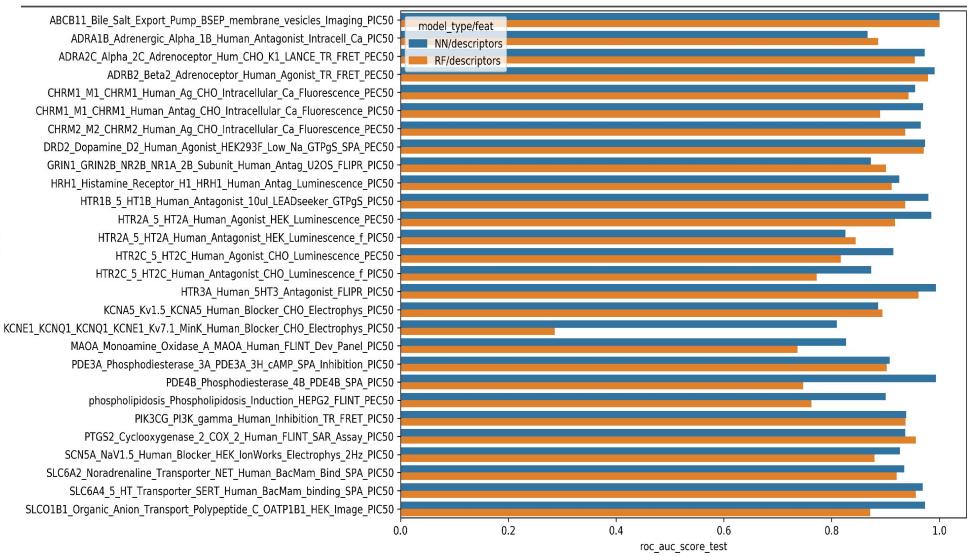

Experimental Design

- Neural Nets and Random Forest Models
- Extended Connectivity FingerPrints (ECFP), Molecular Operating Environment (MOE) descriptor vectors, and GraphConvolution-based features
- NN: Vary learning rates, number of layers, layer sizes, dropout rates
- RF: Vary max depth and number of estimators
- Train iteratively up to 500 epochs and pick best model based on validation set performance

Experimental Summary

- 5,964 total models for 41 Safety and Pharmacokinetic datasets
- •4,696 Neural Net models
- 1,253 Random Forest models
- 3,819 Regression models
- 2,130 Classification models
- Models were trained on a wide range of proprietary GSK assay datasets, including ones that are larger than public datasets reported in the literature

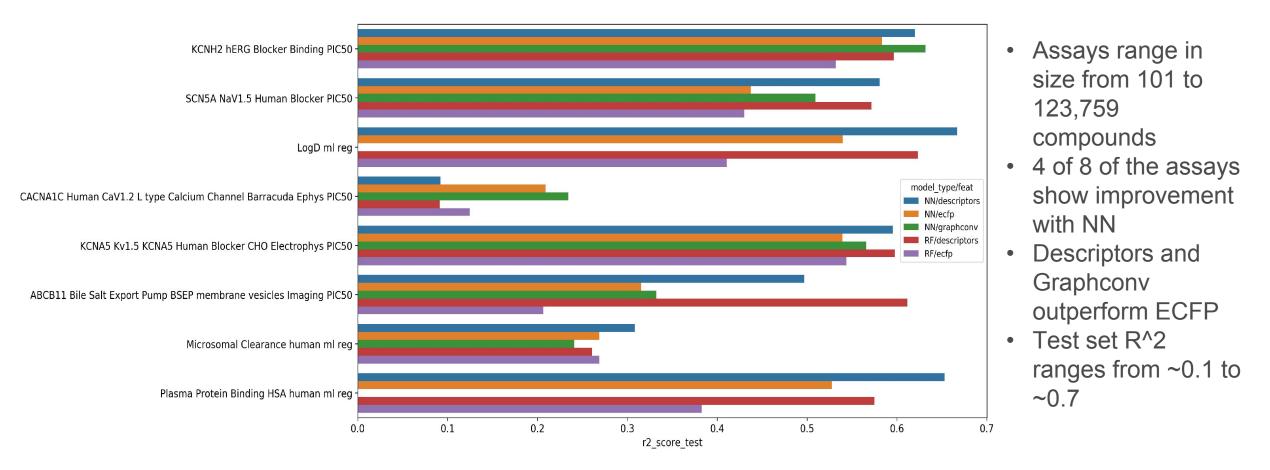

Classification performance shows high accuracy for selected safety targets

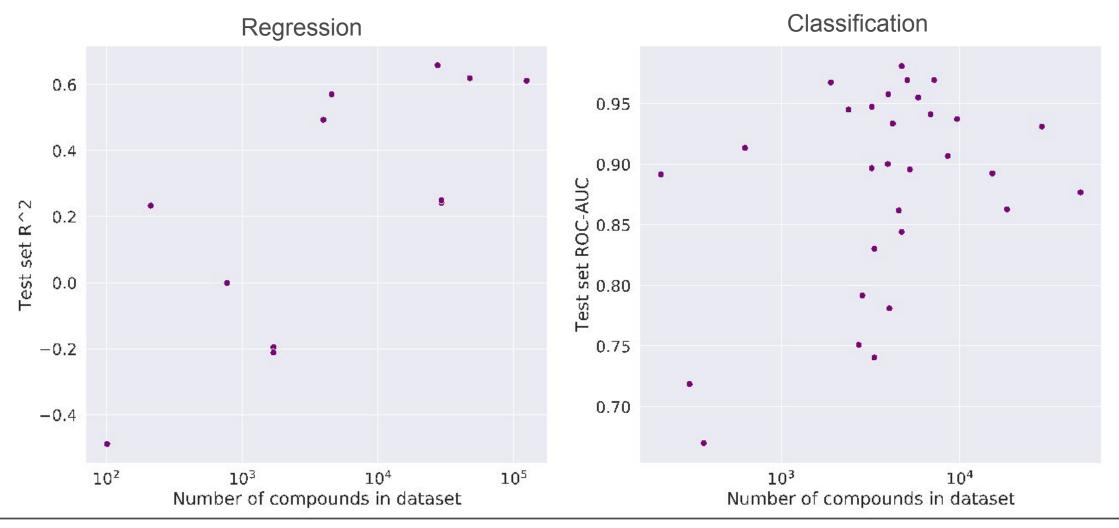

data

- Assays range in size from 187 to 9173 compounds
- 23 of 28 of the assays show improvement with NN
- KCNE1 shows largest improvement
- Classification accuracy appears to be relatively high (>0.8 ROC-AUC)

Regression models present a greater challenge

Test set accuracy varies with number of compounds in dataset

Summary of Observations

- Classification results look good, but need to better handle class imbalance
- Regression models can be improved
- Adding data seems to help, so we are looking into:
 - Sourcing public datasets
 - Generated targeted experimental data
 - Transfer learning
 - Multi-task learning

Uncertainty Quantification (UQ) Analysis

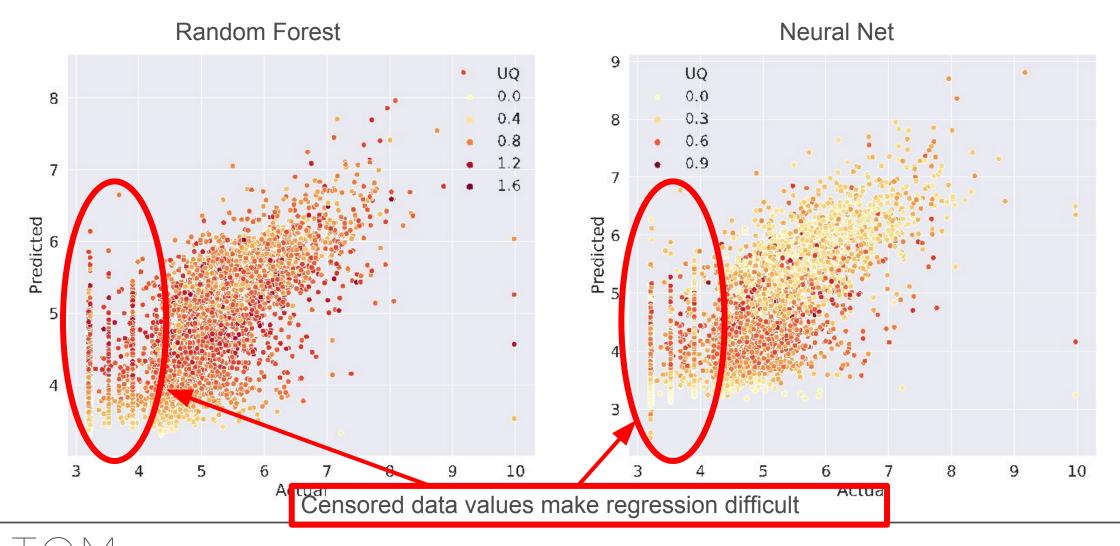

- UQ helps reveal what a model is not confident about
- Goals for data-driven model UQ:
 - 1. Accurately characterize confidence in model predictions as a function of UQ
 - 2. Use UQ to guide active learning
 - 3. Use UQ to weight model ensembles

Modeling uncertainty

- Random Forest
 - Calculate the standard deviation of predictions from individual trees
- Neural Networks
 - Use deepchem's method, which combines aleatoric (sensing uncertainty) and epistemic (model uncertainty) values
 - Aleatoric: Modify loss function and train model to predict both response variable and input variance
 - Epistemic: Apply dropout masks during prediction and quantify variability in predictions

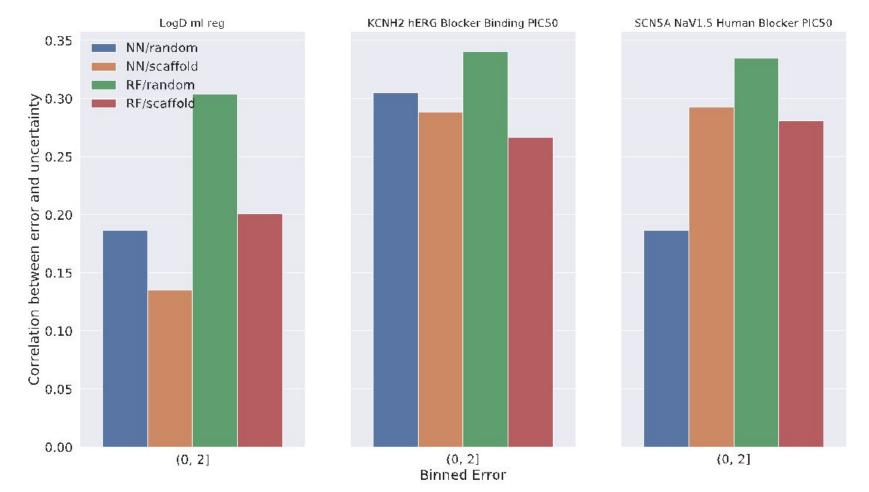

• Then
$$\sigma_{total} = \sqrt{\sigma_{aleatoric}^2 + \sigma_{epistemic}^2}$$

Goal is to quantify prediction uncertainty for assays such as hERG

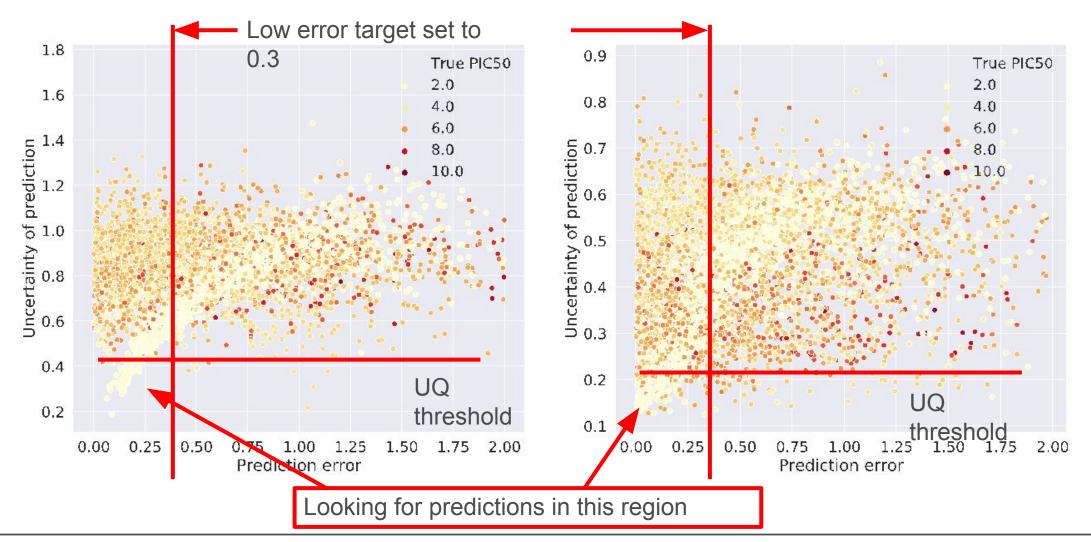

Correlation between error and UQ is fairly low

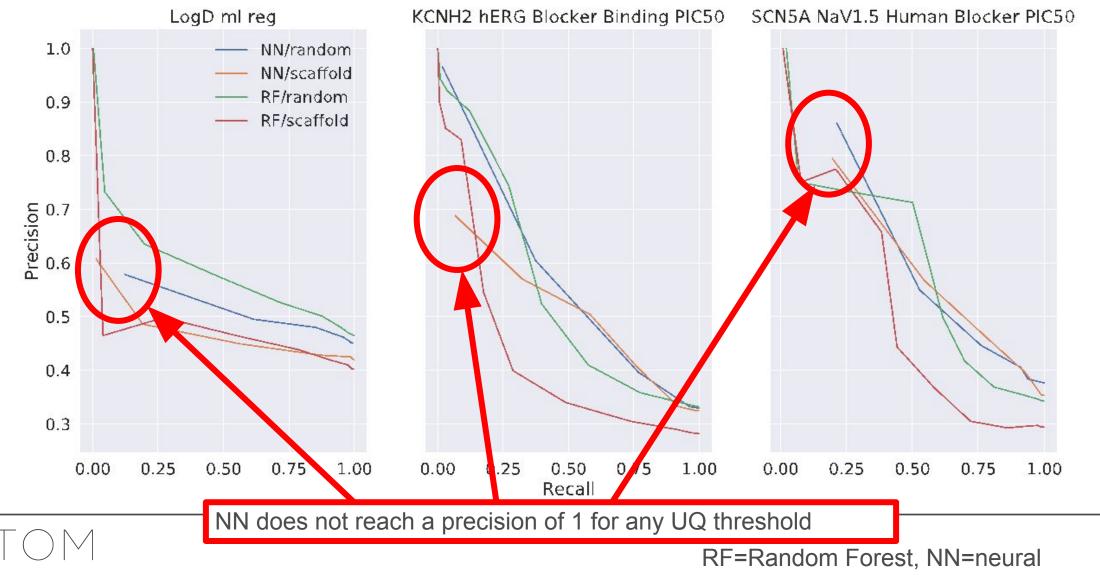

- Binned prediction error
- Kept bins with > 150 samples
- Calculated Pearson's Correlation between error and UQ
- Correlations range between ~0.14-0.35
- All p-values are <<<
 0.01

UQ threshold identifies a fraction of the "low error" predictions, which approximates experimental error

Precision-Recall curves with varying UQ threshold show greater challenges with scaffold splits and neural networks

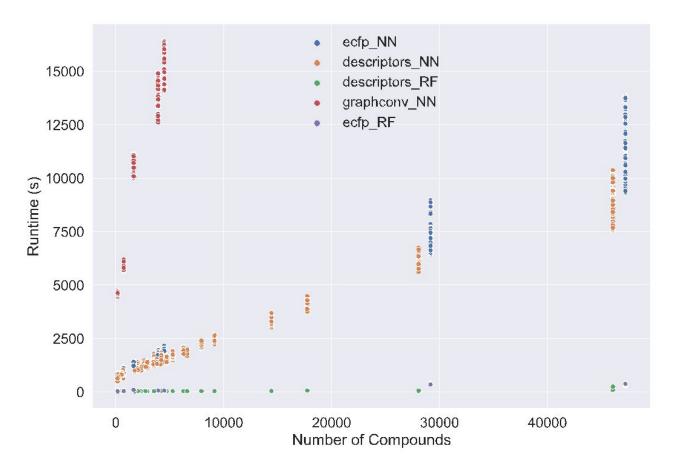

^{. .}

Training time Analysis

- In addition to understanding performance of models, need to understand efficiency
- Examined training runtimes for our models and a variety of variables
- All times were calculated for model building on supercomputers
- Can help to guide future experiments as we scale up

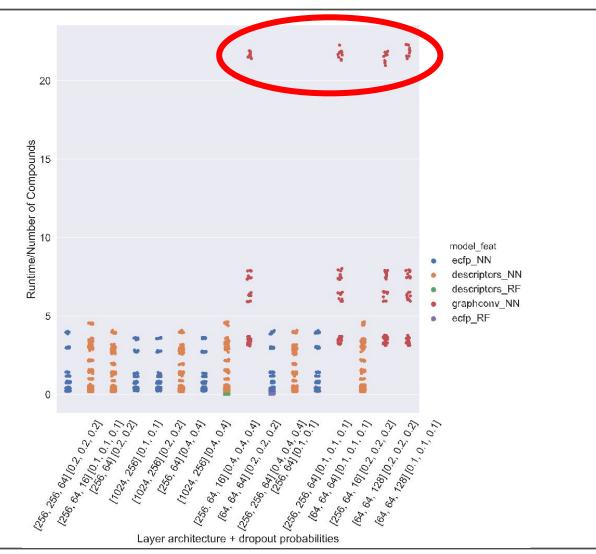

Training time is highly dependent on number of compounds

- Plotted runtime versus
 number of compounds
- Relationship looks linear for NN, with slope depending on feature type
- GraphConv NN models are very slow, while Random Forest is very fast

Layer architecture does not appear to have an effect on training time

- Plotted runtime normalized by dataset size versus Layer Architecture + Dropout Probability Combination
- Surprisingly, number of parameters in network does not affect training time
- Currently investigating why some Graph Convolution models are much slower

Roadmap

- Infrastructure and Architecture what GPUs are we using?
- Data-Driven Modeling Pipeline what have we built?
- Experiments what have we been able to do?
- Future work where are we going from here?

- Pipeline
 - Dev 1.0 release
 - Installable using pip as a whl file
 - Runs internally at GlaxoSmithKline for evaluation
- Models
 - Our models have been incorporated into our *de novo* compound generation active learning loop
 - We are able to export and share models with consortium members as well

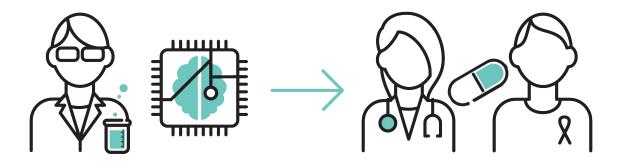

Future Plans

- Improving Portability
 - Release pipeline open source
 - Dockerize the entire pipeline
 - Release data services infrastructure as Kubernetes pods
- Improving performance
 - Add in optimized hyperparameter search function
 - Explore hyperparameters for uncertainty quantification
 - Transfer learning
 - Multi-task learning
 - Ensemble modeling
